Furthermore, it is a fundamental principle to insulate to the greatest level that is justified, based on life-cycle costs, when constructing a building or when retrofitting an existing building. The marginal cost of installing additional insulation is generally low. Higher levels of insulation can be justified during new construction or deep renovation by considering full-system impacts that allow for downsizing of mechanical equipment in accordance with life-cycle cost assessment. The primary drivers that determine optimal levels of insulation are climate, the cost of energy, the heating system type and efficiency, and the installed cost of the insulation.

Synthetic Insulation Materials

This category of insulators presents a very high impact in terms of consumption of non-renewable natural resources, as they derive from the extraction and processing of petroleum. Some, such as insulating products made of polyester fiber, have a lower impact as they derive from recycled polyester from waste sorting of PET bottles.

Expanded polystyrene (EPS) is manufactured by adding pentane (C_5H_{12}) to polystyrene beads, which is then evaporated off to foam the beads. Extruded polystyrene (XPS) is made by melting polystyrene beads and passing the melt through an extruder with the addition of a blowing agent (HFC, C_6H_{12} or CO_2). Polyurethane foam (PUR) is produced by a reaction between a polyisocyanate and a polyether backbone polyol (alcohols containing multiple hydroxyl groups). During the expansion process, the closed pores are filled with an expansion gas (HFC, C_6H_{12} or CO_2). This production process, despite being long and complex, it does not have energy requirements higher than those of insulators of mineral origin, but nevertheless presents a strong impact in terms of atmospheric pollution as regards the reduction of the stratospheric ozone layer, the greenhouse effect, the formation of acid rain and photochemical smog. In particular, the greatest impact on the atmosphere by synthetic insulators has always been due to the use of

the blowing agents such as CFCs and later HCFC and HFC for achieving their cellular structure (EPS, XPS and PUR/PIR), but these are being discontinued due to their high Ozone Depletion Potential (ODP) and Global Warming Potential (GWP). Nowadays, hydrocarbons foaming agents (pentane, isopentane, cyclopentane) are widely used, characterized by zero ODP and a reduced GWP (isopentane's GWP value is 11, compared to 4750 of CFC-11 or 782 of HFC-365mfc). Currently the industry is shifting towards CO₂ and Nitrogen as foaming agents, which advantages compared to hydrocarbons include lower environmental impact (no ODP and reduced GWP), low gas consumption due to their high degree of foaming, low price, non-flammability, non-toxicity and no residue in the finished product. Among those, CO₂ is emerging as the blowing agent of choice since it has much higher solubility in polymers. A further improvement in the reduction of environmental impacts is represented today by the use as raw material of plastics derived from biogas and bio-fuel produced from organic waste or vegetable oils, instead of petroleum, with a saving of CO₂ emissions up to 70% compared to the use of fossil raw materials.

Production of expanded materials still poses a high risk for the health of workers due to possible contact or inhalation of highly toxic substances, such as styrene, benzene, isocyanates, phosgene or phenols, and due to the risk of fires and explosions due to their high flammability.

Regarding the working and installation phase, this does not involve health hazards provided that no hot works are carried out, since the high temperature at which the material is subjected can cause the release of styrene and other decomposition products. On the other hand, the application of polyurethane foams can be extremely harmful, as it causes the release of free isocyanates during in-situ expansion and in the following hours with acute effects on the respiratory tract.

During the operating life of the building, organic compounds can be released in interiors in the first few months after installation, and special attention must be given to the release in case of fire of dense and opaque fumes with highly toxic substances (styrene, benzene, phenols and, in case of PUR, hydrogen cyanide and isocyanates).

If correctly installed, insulators of synthetic origin can have a life span between 30 and 50 years. Re-use is possible whenever the material is not coupled, glued or dirty. Fusion recycling is possible for EPS and XPS but, in fact, only happens in rare cases. Polyurethane, on the other hand, cannot be subjected to a melting process. Expanded insulators are normally recycled by granulation for filling materials or for agglomerates, or subjected to waste-to-energy treatment. Polyester fiber, itself already coming from recycled polyester, is 100% recyclable.

Mineral Insulation Materials

This category of insulators does not present particular impacts from the point of view of the consumption of natural resources, as they derive from raw materials very widespread in nature and available in abundance (quartz sand, clay, minerals of volcanic origin). On the contrary, the mining activity from quarries, if not well managed, can have a strong impact on the territory. Glass wool is normally manufactured with 80% recycled glass (50% of which post-consumption).

The manufacturing process is instead very energy-intensive, due to the thermal production processes at high temperatures (1600°C for stone wool, 1400°C for glass wool and 850–1200°C for expanded granular minerals) which are also responsible for atmospheric emissions from the combustion process. Stone wool is manufactured by melting different kinds of rocks, such as dolostone, basalt and diabase, obtaining fibers that are then bound together with resins, food-grade starches or oils. Glass wool is produced by mixing natural sand and glass (usually recycled). The transformation in fibers occurs via centrifugation and blowing processes then bound with resins.

Since 1995, the health risks for workers and installers of mineral wool manufacture resulting from the inhalation of volatile fibers have been mitigated by the introduction of biosoluble fibers, with limited permanence in the human body and officially considered non-carcinogenic.

During the operating phase of the building, mineral wool can emit volatile organic compounds such as phenols or formaldehyde deriving from the glues and the phenolic or melamine resins used for production. Several glass wool products already employ low-VOC binding agents, of vegetal origin and without added formaldehyde, and stone wool with this technology is currently entering the market. Stone and glass wool are both long lasting and fully recyclable without any reduction in quality.

Bio-Based Insulation Materials

Along with the development of high-tech insulation products, the proposal of natural materials, in the vein of the so-called green architecture, has been growing over time. These materials are expected to be rapidly renewable, of vegetable or animal origin (bio-based materials), possibly recycled or recovered and reused (Schiavoni *et al.*, 2015, 2016). This trend addresses the scope of using environmentally friendly building materials and products that ensure the reuse or recyclability of the construction works, of their materials and of their parts after demolition. The use of bio-ecological insulation is also encouraged by the main environmental buildings certification systems (LEED, BREEAM, Living Building Challenge, etc.), that in fact award points to the project in case of use of renewable, recyclable, recycled materials or materials with recycled content. Using these products aims to reduce the environmental impact of the whole life cycle of materials through greater resource conservation and a reduction of energy consumption and pollutant emissions during production and disposal.

Compared to insulation materials of synthetic and of mineral origin, bio-based insulation materials (animal or vegetable) have, with a comparable performance, lower environmental impact at every stage of the life cycle of the product and a lower embodied energy value (Table 7).

Table 8 Thermal properties of unconventional bio-based insulation materials

Insulation materials	Volume mass Kg m^{-3}	Thermal conductivity $\text{W m}^{-1} \text{K}^{-1}$
Bagasse	70–350	0.046–0.055
Cattail	200–400	0.043–0.060
Cotton (recycled denim)	NA	0.036–0.038
Cotton (stalks)	150–450	0.059–0.082
Cotton (recycled)	25–45	0.039–0.044
Date palm	187–389	0.072–0.085
Durian	357–907	0.064–0.185
Mushrooms	120	0.039
Oil palm	20–120	0.055–0.091
Posidonia seaweed	65–75	0.041–0.044
Pineapple leaves	178–232	0.035–0.042
Reeds	130–190	0.045–0.056
Recycled textile (commercial)	30–80	0.036–0.042
Recycled textile fibers (polyester and polyurethane)	440	0.044
Recycled textile fibers (synthetic)	200–500	0.041–0.053
Rice	154–168	0.046–0.566
Sunflower (pitch)	36–152	0.039–0.050
Straw bale	50–150	0.038–0.067

Note: Schiavoni, S., D'Alessandro, F., Bianchi, F., Asdrubali, F., 2016. Insulation materials for the building sector: A review and comparative analysis, *Renewable and Sustainable Energy Reviews* 62, 988–1011.

Some materials of vegetable origin such as hemp, kenaf, flax, corn, reed, coir and jute derive from easily renewable raw materials, others from recycled raw materials and processing waste (cellulose and wood). Cork is a renewable raw material but of limited availability (the plant can be decorticated only every 8–10 years). For the production of some particular products (hemp, kenaf, cellulose, flax, sheep wool), a percentage of synthetic fiber, generally polyester, may be added to the main fiber in a measure of 10%–15% up to 50% for support or reinforcement.

In addition to the more traditional renewable insulation materials, innovative products made with fungi roots, wood foam, marine algae or the fibers of recycled jeans are currently being researched (Casini, 2016) (Table 8). Mushrooms roots (mycelium) insulation materials are grown from agricultural and food waste, obtaining a material with good thermal performance, inherently flame retardant and stable over time that does not need chemical additives, thus containing VOC emissions. Among the insulators of vegetal origin deriving from recycled raw materials or processing wastes, in addition to wood, particularly interesting are those that use textile fibers or recycled cellulose. Recycled cellulose comes from waste and by-products of paper processing as well as returned newspapers. Recycled textile insulation materials are also gaining interest, in particular referring to fibers of jeans recycled pre-consumer (waste from the production) or post-consumer (denim insulation). Regarding sheep wool, the one used in building applications comes from flocks bred for meat and milk production, not for the textile industry, and would otherwise be wasted.

The production process generally has a low or almost zero environmental impact, with the exception of those insulators requiring a heat treatment such as mineralized wood fiber and expanded cork. In particular, mineralized wood fiber panels have a significant consumption determined by the production of the Portland cement binder used to manufacture the panels that account around 50% weight (the production process provides the mixing of fir wood fibers with cement followed by a drying phase).

As far as the operating phase is concerned, possible health risks may derive from the emission of powders and fibers, or from the release of any toxic substances used for adhesives (cork, wood fiber). Furthermore, for some materials, the presence of residual insecticide or pesticide used in intensive cultivation and farming (flax, hemp, sheep's wool) or preserving treatments to protect the material during long-distance transport (coconut, jute) may be an issue. Substances contained in sheep wool fibers are instead able to absorb indoor pollutants such as formaldehyde, VOCs, nitrogen oxides (NO_x) and sulfur oxides (SO_x). This is due to the presence of keratin, a base component of the albumin protein that constitutes the wool: molecules from lateral groups of its amino acids can bond with polluting agents and degrade them into harmless substances.

Regarding the recovery or recycling of materials after the phase of disposal, this can be made problematic, if not impossible, by the presence of binders (mineralized wood fiber), additives (addition of synthetic fibers), fireproofing or anti-parasitic treatments (sheep wool), or glues or adhesives used for installation (cork and wood fiber).

Fiber Reinforced Aerogel Blankets

FRAB composition is made normally of 40%–55% silica, 20%–45% PET/glass fiber and 0%–15% additives. The manufacturing process first impregnates a fibrous felt with silica sol-gel solution (sol-gel casting); when impregnation is complete, felts are rolled and placed in a controlled environment for chemical ageing of the gel. Finally, supercritical extraction of the solvent is carried out in large autoclaves with CO_2 recovered from other external industrial processes. As the gel dries, aerogel particles are firmly

Table 9 FRAB environmental characteristics

<i>Component</i>	<i>Embodied energy (MJ/kg)</i>	<i>Embodied CO₂ (kg/kg)</i>
Silica precursor and other raw materials	35.5	3.2
Fibrous reinforcement	12.1	0.6
Production process	3.5	0.4
Supercritical extraction	2.1	Recovered from other industrial processes
Pollution control equipment	0.7	0.03
Total	53.9	4.23
International transport (from US to Europe)	2.2	0.14

Note: ASPEN AEROGELS, 2015. Spaceloft[®] Aerogel Insulation Environmental Product Declaration According to ISO 14025 and EN 15804. Declaration Number S-P-00725. Anglesey: Renuables Ltd.

embedded into the mat fibers. After a final drying step an aerogel saturated mat, easy to transport and install, is achieved. FRABs can then be coupled with support materials such as rigid PP panels.

From an environmental point of view, FRABs require a relatively modest 53.9 MJ/kg for manufacturing (embodied energy), compared to 88.6 MJ/kg for expanded polystyrene and 101.5 for polyurethane foam. Most energy is needed for obtaining and mixing silica precursor and other raw materials for the sol gel solution. Conversely, embodied CO₂ amounts to 4.23 kg per kg of finished product, of which 3.2 kg are required by solution preparation alone (see [Table 9](#)).

Moreover, FRABs are completely innocuous to the ozone layer (Ozone Depletion Potential ODP = 0), employ recycled materials and are further completely recyclable, are lead free and ROHS compliant and release zero VOC ([ASPEN AEROGELS, 2015](#)). Finally, their excellent aging resistance, measured by accelerating aging techniques (12 weeks at 90°C, equal to 60 years in real world conditions, showed no decay in insulating performance) ensure maintenance free operating life and the possibility of further reuse of the products.

Regarding the installation phase, FRABs tend to produce dust during movement and installation, but this is not considered harmful to health as it contains silica in amorphous and not crystalline form, posing no carcinogenicity concerns according to the International Agency for Research on Cancer (IARC). However, dust coming from aerogel blankets manipulation may cause mechanical irritation to the upper respiratory tract and its high hydrophobicity strongly dries skin and may damage lubricated parts of machines used for processing and installation. Mats encapsulation with rolled flame retardant polymers was proved as a viable solution of this issue causing little increase of thermal conductivity (from 0.018 to 0.020 W/mK).

Conclusions

The role of thermal insulation is fundamental to achieve the objectives of zero energy building in both new constructions and retrofit interventions and of the consequent reduction of global CO₂ emissions. A more effective insulation of buildings will also bring significant environmental, economic as well as social benefits for both public administrations and for citizens.

Many different solutions are currently available on the market. The choice of the most suitable insulation material or installation technology depends on the type of application and the operating conditions and have to take into account technical, economic and environmental aspects.

Future scope concerns the development and characterization of improved insulation materials and solutions based on advanced sustainable materials and/or nanotechnologies to provide enhanced insulation properties and environmental performance, addressing issues such as thermal bridges correction and ensuring the best architectural quality. In particular, room for improvement regards reduced embodied energy, that, in perspective of more and more energy efficient buildings, will assume a greater weight in the overall lifetime energy balance.

LCCA and Environmental Impact of Buildings

Hina Zia, Jamia Millia Islamia, New Delhi, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Globally, countries increasingly recognize the relevance and importance of mainstreaming green buildings for various reasons, one of them being this happens to be a low hanging fruit when it comes to carbon mitigation efforts and the additional benefits of low operational costs and other associated benefits. In spite of the wide recognition and relatively larger adoption of various environmental rating systems and building energy codes (voluntary or mandatory) by different countries all over the world, green buildings as part of the total new/existing building stock continues to be low. As per a recent report released by [IEA and UNEP \(2018\)](#) the spending on energy efficiency and greening of buildings has been slowing down with incremental energy efficiency investment increasing by only 4.7% in 2017 compared to 6%–11% annual growth rates observed from 2014 to 2016. There continues to be a prevailing perception of high (initial) costs associated with green buildings. LCCA or Life Cycle Cost Analysis is one of several methods to rationally look at the potential cost savings of a product, system or building as a whole over its assumed life compared to various alternatives. What sets it apart from simple payback calculation (and therefore an effective decision making tool) is it not just considers the enhanced cost of the product/system/building component but also accounts for hidden costs such as future costs of maintenance, operation costs, energy use, salvage and replacement value. It thus gives a logical way of taking decisions and has the potential (if applied extensively) to largely get over the myth that green buildings cost more. If LCCA is made more popular, it will be more convincing for acceptance by the financier/banker on identifying the more valuable buildings.

There is another similar sounding (yet different) popular tool called LCA or Life Cycle Analysis which provides an assessment of a product, system or building's sustainability over the entire life cycle. It looks at more accurate assessment of materials true environmental impact over the entire life cycle. LCA estimates the environment impact in terms of greenhouse gas emissions, wastes, toxins, and particulate matter. LEED v4 has given a new impetus to considering LCA by including them in the Materials and Resources section.

LCA when combined with LCCA gives the most rounded analysis. Given the spurt of activities already going on around LCA (and the materials section in LEED), there is a need specially in developing economies like India where initial costs and payback are the key drivers for decision making to look at LCCA more rigorously and actively.

Aim

The paper attempts to analyse the incremental costs of select residential (multi-family high-rise) projects in India certified under the Energy Efficient Homes (EE-Homes) programme between 2012–2015 and to assess the economic feasibility of energy-efficient buildings using the LCCA approach. The German development bank, *KfW Entwicklungsbank*, provided a line of credit in 2012 to the *National Housing Bank of India (NHB)* to promote energy efficiency in the residential building sector in India. This credit line was used by NHB for refinancing individual home buyer loans for energy-efficient new residential housing under the *Energy Efficient Homes Programme*. Apartments eligible for refinancing had to meet a minimum standard of 30% improvement over the benchmark building in energy efficiency if active Energy Efficiency measures are implemented, and 18% improvement if only passive Energy Efficiency measures are applied. Projects meeting the target received an official certificate under the programme.

There are two important perspectives when looking at the incremental costs of energy-efficient buildings:

- (1) From the construction point of view EE is particularly relevant for the investors of buildings, since their overall goal is to construct in a cost-efficient way.
- (2) From a macroeconomic point of view it is more relevant to not only look at the incremental costs in the construction phase, but to also look at the incremental costs over the entire life cycle.

Therefore, future streams of benefits arising from energy savings were also evaluated and reflected in the lifecycle assessment of incremental costs in order to assess the economic viability of investments made towards improving the energy performance of buildings.

Life Cycle Costing-Concept

Life-cycle costing (LCC) is a method for assessing the total cost of facility ownership. It takes into account all costs of acquiring, owning, and disposing of a building or building system. LCC is especially useful when project alternatives that fulfill the same performance requirements, but differ with respect to initial costs and operating costs, have to be compared in order to select the one that maximizes net savings ([Fuller and Petersen, 1995](#)).

LCC can be implemented at any level of the design process and can also be an effective tool for evaluation of existing building systems. LCC can be used to evaluate the cost of a full range of projects, from an entire site complex to a specific building system component.

Methodology

Using the standard methodology (Fuller and Petersen, 1995) to analyse the incremental costs of EE measures for the four buildings studied, all costs for the actually constructed buildings, i.e., the “green” (actual) case, were compared to the costs of the benchmark buildings, i.e., the “reference” case. Both incremental costs for the construction itself and over the entire life cycle of the building were assessed. Also, the financial indicator, Discounted Payback Period was determined for the implemented measures, in order to assess the economic viability of the Energy Conservation Measures (ECMs).

Multiple realistic assumptions have been made, the case (i.e., the actual/green case and the reference case) has been defined, and sources for data have been chosen. The following sections describe the methodology applied in detail.

Green (actual) case and reference case

More than 15 residential projects located in various climatic zones of the country participated in the Energy Efficient Homes programme and were able to achieve the minimum desired level of energy savings as prescribed in the programme. Of the various projects situated in different representative climate zones, four specific projects have been selected to study the incremental costs of these energy-efficient buildings using the LCC approach. These projects are:

- (1) Ganga Skies, Pune (Moderate climate)
- (2) Spire Wood, Gurgaon (Composite climate)
- (3) Apollo HIRCO, Mumbai (Warm and Humid climate)
- (4) Lotus Boulevard, Noida (Composite climate)

The parameters for building design, system, lighting power density, use of solar water heaters, and thermo-physical properties of building envelope were assessed during the certification of these projects. For conducting the comparative analysis, parameters regarding the way of construction of the reference case were used as defined during the IT Toolkit development. The parameters of the reference buildings (as of the IT Toolkit) can be found in Annexure A. **Table 1** below illustrates the ECMs implemented in these four buildings (green case):

Costs included in life cycle costing and data sources

There are numerous costs associated with acquiring, operating, maintaining, and disposing of a building or building system. Building-related costs usually fall into the following categories:

Table 1 Energy conservation measures used in the projects which added to the incremental capital investments

Ganga skies^a	● Use of Autoclaved Aerated Concrete (AAC) block instead of brick masonry for walls ● Roof insulation and reflective paints on the roof ● Use of 6 mm reflective glass
Spire woods^b	● Use of AAC block instead of brick masonry for walls ● Roof insulation and reflective paints on the roof ● Use of 6 mm reflective glass ● Provision of solar hot water systems ● Provision of 4-star AC
Apollo HIRCO^b	● Use of AAC block instead of brick masonry for walls ● Roof insulation and reflective paints on the roof ● Use of 6 mm reflective glass ● Provision of solar hot water systems ● Provision of 4-star AC
Lotus boulevard^a	● Use of AAC block instead of brick masonry for walls ● Roof insulation and reflective paints on the roof ● Use of 6 mm reflective glass

^aAny reduction/addition of incremental costs due to reduced common area lighting power density and reduced structural load (due to AAC) has not been considered.

^bAny reduction/addition of incremental costs due to reduced common area lighting power density, internal lighting power density and reduced structural load (due to AAC) has not been considered.

Table 2 Data sources/definitions of different costs

Costs	Green (Actual) case/Reference case
Construction costs/investment costs	CPWD Plinth area rates and Schedule of Rates, market rates for components such as SWH, AC
Energy costs	Average tariff rates for domestic sector
Operating, maintenance and repair costs	Assumed to be 2% of the capital costs per year (based on discussions with sectoral experts)
Residual costs	Residual costs are the remaining value of the initial investment cost (excluding the land cost) at the end of 15 years. It has been assumed as 6% of the initial investment cost which increases @8% per year (This information was provided by financial experts)

Source: Author.

- Initial Costs – Purchase, Acquisition, Construction Costs
- Operation, Maintenance, and Repair Costs
- Replacement Costs
- Residual Values – Resale or Salvage Values or Disposal Costs
- Energy Costs

Only those costs within each category that are relevant to the decision and significant in amount are needed to make a valid investment decision. Costs are relevant when they are different for one alternative compared with another; costs are significant when they are large enough to make a credible difference in the LCC of a project alternative. All costs are entered as base-year amounts in today's currency; the LCCA method escalates all amounts to their future year of occurrence and discounts them back to the base date to convert them to present values (Gluch and Baumann, 2003).

Following categories have been used for the calculations in this study: (1) construction/ investment costs, (2) operating, maintenance and repair costs, (3) residual costs (4) energy costs, which are derived from specific data sources. Table 2 provides a summary of the data sources of these four different cost categories:

The following subsections describe the data sources used for calculation of incremental construction costs and Life Cycle Costs (LCC) of both the green and the reference case in more detail.

Construction costs

In the absence of the actual Bill of Quantities (BOQ) and rates used by these projects, the following data sources were used to calculate overall construction costs from different cost components:

- Civil construction: Plinth Area Rates as given by Central Public Works Department (CPWD) were used for the calculation of civil construction costs (see "Relevant Websites section").
- Masonry, glazing, roof insulation and paints: The CPWD Schedule of Rates 2012 was used (see "Relevant Websites section").
- SWH rates and star ACs: Average available market rates from vendors were used.
- Thumb rules were used for calculation of other costs such as (This information was provided by sectoral experts):
 - Internal water supply and sanitary installations (12% of civil construction costs);
 - External service connections (5% of civil construction costs); and
 - Internal electric installations (12.5% of civil construction costs).

There may be variations in the actual rates depending on regional markets; however, CPWD seems to be the best available, most comprehensive and most current schedule prepared by a government entity (The escalation cost due to reduced lighting power density on account of possible better lighting fixtures is not considered due to absence of detailed information on fixture types, number, etc).

Energy costs

An average tariff rate of 5.5 Rs/KWh is assumed for all the cases considered (for a consumption volume of 201–400 kWh/month for the residential sector), although from state to state these rates differ and change every financial year (For more details please refer to the different state regulatory commissions' websites available at "Relevant Websites section"). Please note that applying fixed (discounted) electricity prices for the calculations is rather a conservative approach, since the (net) energy price is expected to increase significantly over the next years and decades.

Operating, maintenance and repair costs

Operating, maintenance and repair costs are assumed to be 2% of the investment cost per year (This assumption is based on discussions with experts from the sector). This reflects higher expected operating, maintenance and repair costs for the ECM.

Residual costs

The resale value (excluding the land cost) for the project is assumed to be 6% of the initial investment cost, which increases by about 8% annually. Other residual costs have not been considered. Since a LCC is a summation of costs, a negative residual value indicates that there is value associated with the building at the end of the study period. Perhaps, the value is a roof that was recently replaced or it is the building's superstructure that could function for another thirty years. Whatever the reason for the remaining value, it is a tangible asset of building ownership and should be included in the LCCA.

A positive residual value indicates that there are disposal costs associated with the building at the end of the study period. Perhaps, the costs are related to abatement of hazardous material or demolition of the structure. Whatever the cause, these are costs of building ownership and should be included in the LCCA.

Zero residual value indicates that there is no value or cost associated with the building at the end of the study period. This rare instance occurs if the intended use of the building terminates concurrent to the end of the study period, the owner is unable to sell the building, and the owner is able to abandon the building at no expense.

Formulas applied

In order to calculate the incremental costs for initial incremental investments, the discounted payback period of projects and the incremental costs over the life cycle, the following formulas have been applied based on The National Institute of Standards and Technology (NIST) Handbook 135 (1995 edition):

Assessment of initial incremental investment

$$\text{Initial incremental investment} = I_{\text{energy efficient case}} - I_{\text{conventional case}}$$

Where,

$I_{\text{energy efficient case}}$ = all costs occurred for the construction of the EE building as specified above

$I_{\text{conventional case}}$ = all costs occurred for the construction of the reference building as specified above

Discounted payback period

Discounted payback period = time required for cumulative savings to recover initial incremental investment, taking the time value of money into account

Where,

$$\text{Annual savings}_t = (\Delta E_t + \Delta \text{OM\&R}_t + \Delta \text{Res}_t)$$

$$t = 1, 2, \dots, 15$$

The life time of buildings is assumed to be 15 years in these calculations, although the actual life time of a building is much longer, potentially in the range of 25–50 years. However, since it is expected that buildings undergo major repair after 15 years, this time period is considered here.

Life cycle cost calculation

Life cycle cost (LCC) analysis is a measure to calculate the total cost of a building over its entire life time. It is a useful tool to compare cost-effectiveness of EE projects with that of conventional projects as it estimates the total cost of a building over its entire life. The general formula used for LCC calculation is:

$$LCC = I + E + \text{OM\&R} - \text{Res}$$

LCC = Total Life cycle cost of the building in current value rupees

I = Present value investment costs (All initial investments costs are considered to be incurred at the beginning of the study period)

E = Present value of energy costs

$\text{OM\&R}$ = Present value of non-fuel operating, maintenance and repair costs

Res = Present value of residual costs value (Residual costs refer to the net worth of a building at the end of the LCCA study period.

Unlike other future expenses, an alternative's residual value can be positive or negative, a cost or a value)

In order to calculate the present values (Refer Annexure B) for energy, OM&R costs, and resale value, the following parameters are used ([Table 3](#)):

Table 3 Discount, inflation and escalation rates used

Parameters	Values
Nominal discount rate (D)	16%
Real discount rate (d)	10.6%
Inflation rate (I)	4.9%
Nominal escalation rate (E)	7.6%
Real escalation rate (e)	2.6%

Source: Author.

Sensitivity analysis to study the impact of change in discount rates and escalation rate of energy prices has not been done in the current study due to time constraint.

Incremental Costs for Construction of EE Buildings

The following **Table 4** presents the results of the incremental costs analysis of the buildings studied regarding investment costs, energy costs and respective energy savings through ECMs as well as the payback periods for these four projects. It can be highlighted that the green (actual) cases of the Spire Woods and the Apollo HIRCO projects cause the highest incremental investment costs – with 2.02% and 2.8% respectively – but at the same time also achieve the greatest energy savings (36% and 32% respectively).

If further analysis is done regarding the incremental capital costs incurred per sq. m in case of an energy efficient building versus a conventionally built building, it is observed that the incremental costs per sq. m ranges between Rs 232–942 in the studied four projects. The average selling price of residential apartments in Class 1 towns and cities in India is Rs 55,000/sq. m. Hence, the incremental costs compared to the selling price are relatively low (**Fig. 1**).

The following **Table 5** gives the list of Energy Conservation measures (ECMs) used in the studied projects which are responsible for the incremental capital costs.

It is further seen that the incremental costs for using more efficient AAC blocks are very low. Only in-cremental costs of about 1% have to be invested using AAC instead of conventional bricks. Costs for improving the thermo-physical properties of the roof are also rather small, whereas costs for use of more energy-efficient glazing and provision of solar water heaters are rather substantial.

Table 4 Results of incremental costs analysis

Building name	Climate zone	Cases (reference/green)	EPI (kWh/m ² /yr)	Energy savings (%)	Investment costs (in crore rupees)	Incremental investment cost (%)	Energy costs per year	Payback period (years)
Ganga skies	Moderate	Reference case	71	–	Rs12.37	–	Rs 1,727,963	
		Actual (green) case	55	23%	Rs 12.48	0.9%	Rs 1,338,563	1.5
Spire woods	Composite	Reference case	69	–	Rs 18.49		Rs 3,092,958	
		Actual (green) case	44	36%	Rs 18.85	2.02%	Rs 1,519,760	2.2
Apollo HIRCO	Warm and Humid	Reference case	95	–	Rs 12.39		Rs 1,848,605	
		Actual (green) case	65	32%	Rs 12.73	2.8%	Rs 1,264,835	3
Lotus boulevard	Composite	Reference case	102		Rs 23.20		Rs 3,847,338	
		Actual (green) case	82	20%	Rs 23.38	0.8%	Rs 3,092,958	1.3

Table 6 Overall incremental construction costs

	<i>Ganga skies</i>	<i>Spire woods</i>	<i>Apollo HIRCO</i>	<i>Lotus boulevard</i>
Incremental costs	Rs. 1,027,438	Rs. 3,608,938	Rs. 3,331,842	Rs. 1,807,180
(% of investment costs)	0.87%	2.02%	2.83%	0.80%

Source: Author.

Overall, the incremental construction costs for the four buildings ranged from 0.8% to 2.83% compared to the costs of the reference case (Table 6). Higher incremental costs in Spire woods and Apollo HIRCO is due to the provision of solar water heaters and 4-star AC.

Incremental Costs for EE Buildings Over Entire Life-Cycle

The following Table 7 gives an overview of all cost categories, the overall LCC as well as the total LCC savings over the reference cases.

In all cases it can be observed that the LCC of the energy-efficient building is lower than the LCC of the same building built with conventional construction practices. Even though the initial investment costs for energy-efficient buildings is higher than that of conventional buildings, over the life span of 15 years (the actual life span of a building is more likely 25–50 years, but 15 years were used for the calculations in this study) an energy-efficient building turns out to be significantly cheaper than a conventionally built building. The annual savings realized in an energy-efficient building more than compensate for the initial incremental costs incurred by incorporating ECMs in a building's construction.

Fig. 2 shows the comparison between LCC of energy-efficient cases and those of the respective reference cases for the four case studies.

Discounted Payback Period

Discounted payback period (DPP) is the time required to recover the initial incremental investment from the discounted future savings. To calculate the DPP, present values of annual savings are cumulated until they equate with the initial incremental

Table 7 Overview of different costs and LCC savings of studied projects

<i>Building name</i>	<i>Climate Zone</i>	<i>Case (reference/green)</i>	<i>Investment costs</i>	<i>Energy consumption over lifecycle</i>	<i>Operating, maintenance and repair costs over lifecycle</i>	<i>Residual value over lifecycle</i>	<i>Overall LCC</i>	<i>LCC savings total (and in % of investment cost of reference case)</i>
Ganga skies	Moderate	Reference case	Rs. 123,737,908	Rs. 15,059,166	Rs. 20,042,591	Rs. 6,537,093	Rs. 152,302,573	–
		Green (actual) case	Rs. 124,765,346	Rs. 11,665,551	Rs. 20,209,012	Rs. 6,591,372	Rs. 150,048,537	Rs. 2,254,036 (1.48%)
Spire woods	Composite	Reference case	Rs. 184,887,570	Rs. 20,642,470	Rs. 27,215,893	Rs. 7,783,551	Rs. 224,962,383	–
		Green (actual) case	Rs. 188,496,508	Rs. 13,163,314	Rs. 27,747,137	Rs. 7,935,483	Rs. 221,471,477	Rs. 3,490,906 (1.55%)
Apollo HIRCO	Warm and humid	Reference case	Rs. 123,941,025	Rs. 16,011,587	Rs. 18,244,416	Rs. 5,217,773	Rs. 152,979,255	–
		Green (actual) case	Rs. 127,272,867	Rs. 10,955,296	Rs. 18,734,871	Rs. 5,358,039	Rs. 151,604,994	Rs. 1,374,261 (0.9%)
Lotus boulevard	Composite	Reference case	Rs. 231,945,173	Rs. 33,323,498	Rs. 34,142,885	Rs. 9,764,621	Rs. 289,646,936	–
		Green (actual) case	Rs. 233,752,353	Rs. 26,789,479	Rs. 34,408,906	Rs. 9,840,702	Rs. 285,110,037	Rs. 4,536,899 (1.57%)

investment. When using DPP as an assessment criterion, an investment is profitable if its discounted payback is lower than the life of the product (15 years considered in this study although it is higher in the range of 25–50 years).

Fig. 3 clearly illustrated that all the four cases have DPP between 0.8 and 2.8 years.

Summary

The study shows that investing in EE buildings is a profitable venture and use of LCCA gives a better perspective of taking right decisions. Using the LCCA for the selected four projects, all the energy-efficient projects have proved to be financially attractive.

Incremental costs for using better walling and roofing alternatives such as AAC and insulation/reflective paints for the roofs are relatively small, while EE glazing is much more costly. However, total incremental costs of the green case over the reference case are in the range of 232–942 Rs/sqm, which are very low compared to an average selling price of 55,000 Rs/sqm.

With incremental costs ranging between 0.8% and 2.8% of the initial capital investment, the discounted payback periods are notably attractive ranging between 1.3 and 3 years. Overall, cash savings accrued from these energy-efficient apartments not only compensate for this initial cost increment but provide benefits to the owners throughout the life time of the building.

In the developer driven (residential) market, there is often a debate between split incentives with the developer bearing the incremental costs whereas dividends through conserved energy are reaped by the home buyers/owners. This remains one of the key

barriers in the market of green construction. However, this obstacle can be overcome with enhanced awareness, incentive schemes, policy support, and other promoting measures for energy efficiency among the buyers, as developers have to respond to user needs and demand, while potentially charging a premium for the higher costs incurred. The KfW-NHB EE Homes programme attempted to achieve this through various measures including financial incentives. Lessons learnt from such programmes can be replicated and integrated with mainstream policies and programmes at the Federal and State level for larger uptake.

With the launch of the new Eco-Niwas Samhita 2018 in India, also known as Energy Conservation Building Code for Residential Buildings, adopting LCC approach as shown by this study to overcome the perceived barrier of high costs associated with green/energy efficient buildings particularly in residential sector is even more relevant and pertinent. It is strongly recommended to make LCCA a formal part of construction process as is the practice in some parts of the world to let various stakeholders take more rational decisions of investing in green building and energy efficiency features.

Annexure A

Reference Building Parameters

For the reference case, the tool includes pre-defined values for the building envelope and systems which represent the common building practice for urban residential housing construction. In order to calculate and certify an actual “energy efficient building”, the Assessment Tool user enters all active and passive energy efficiency measures applied in the building. Through the tool, the energy consumption of the reference case and of the actual energy efficient building are simultaneously being calculated and compared.

The tool reference case, against which the actual building is being assessed, is currently defined as:

Building envelope

External Wall

Conventional External Wall

U-Value 1.57 W/(sq. m K)

Roof

Flat Roof (conventional roof)

U-Value 1.77 W/(sq. m K)

Floor (floor of the lower most apartment)

Lowest Level Apartment Floor

U-Value 2.03 W/(sq. m K)

Glazing

Single clear

U-Value 6.17 W/(sq. m K)

SHGC (Solar Heat Gain Coefficient) 0.81

Window frame

Aluminium without thermal break

U-value 13.51 W/(sq. m K)

Shading by overhangs and fins

SHGC (Solar Heat Gain Coefficient) 0.9

Lighting

Lighting Power Density for the general lighting scheme shall be taken as 7.5 W/m² for the apartment area, 6.5 W/m² for common area lighting and 2.2 W/m² for parking area lighting.

No occupancy/daylight controls

Lighting operation schedule – 6–9 morning, 17:30–23:00 evening, 60% diversity

Space cooling

The base case cooling system shall be BEE 1 star rated product having minimum EER of 2.5 W/W for decentralized cooling systems.

A central (VRF) system shall have an EER of 3.9 as there is not yet a star rating available.
 Cooling operation schedule – 8 h/day, 70% diversity, 1st May – 15th October
 Cooling set point temperature – 25°C

Space heating

The space heating is not changed in the reference building.

Hot water system

The hot water systems are left as they are except for electric geyser which shall have a BEE 1 star rating.
 If the actual building has SWH it will be removed in the reference building.

Annexure B

Present Value Factors (Fuller and Petersen, 1995)

Single Present Value is used to discount the single costs of the project i.e., initial investment cost, and resale value of the project. Uniform Present Value is used to discount the uniformly annually recurring costs of the project i.e., OM&R costs of the project. Uniform Present value-non-escalating is used to discount the non-uniform annually recurring costs of the project i.e., energy costs that change from year to year at a constant escalation rate.

Single Present Value PV of a future cash amount occurring at the end of year t , F_t , given a discount rate d :

$$PV = F_t \times \frac{1}{(1+d)^t}$$

Uniform Present value PV of a series of equal cash amounts, A_0 , that recur annually over a period of n years, given d :

$$PV = A_0 \times \sum_{t=1}^n \frac{1}{(1+d)^t} = A_0 \times \frac{(1+d)^n - 1}{d(1+d)^n}$$

Uniform Present value non-escalating PV recurring annual amounts that change from year to year at a constant escalation rate, e over n years, given d :

$$PV = A_0 \times \sum_{t=1}^n \left(\frac{1+e}{1+d} \right)^t = A_0 \frac{(1+e)}{(d-e)} \left[1 - \left(\frac{1+e}{1+d} \right)^n \right]$$

The different Present value factors calculated and used for LCC in this study is given as under (Table B1):

Table B1 Present value factors calculated and used for LCC

Year	Uniform present value factor-escalating	Single present value factor (SPV)	Uniform present value factor-non escalating
1	0.9043	0.9043	0.9276
2	1.7221	0.8178	1.7880
3	2.4616	0.7395	2.5861
4	3.1304	0.6688	3.3264
5	3.7351	0.6048	4.0131
6	4.2820	0.5469	4.6501
7	4.7766	0.4946	5.2410
8	5.2238	0.4472	5.7890
9	5.6283	0.4044	6.2974
10	5.9940	0.3657	6.7690
11	6.3248	0.3307	7.2064
12	6.6239	0.2991	7.6121
13	6.8943	0.2705	7.9885
14	7.1389	0.2446	8.3376
15	7.3601	0.2212	8.6614

Leadership in Energy and Environmental Design Rating System: A Global Tool to Assess Sustainability in Buildings, Communities and Cities

Mili Majumdar, Green Business Certification Institute, India and U.S. Green Building Council, Washington, D.C., United States

© 2020 Elsevier Inc. All rights reserved.

LEED, Leadership in Energy and Environmental Design stands for the most globally relevant and accepted green building rating system designed and administered to transform buildings to be sustainable and healthier, change behavior and facilitate healthy spaces that do no harm to people. Developed by U.S. Green Building Council, LEED has been applied in 167 countries. USGBC leads by example and has a strong vision that buildings and communities will regenerate and sustain the health and vitality of all life within a generation. LEED has set global benchmark and standard for facilitating design, construction and operation of green and sustainable buildings, communities and cities and most importantly addressing health aspects of people working in or living in their buildings. LEED, is a performance driven rating system that holistically addresses all aspects of building or project life cycle from how conveniently it is located to intrinsic aspects of indoor environmental quality such as daylight, quality views and indoor air quality and acoustics.

The LEED Rating System is a voluntary, consensus driven, internationally recognized green building certification system providing third-party verification that a building or community was designed and built using strategies aimed at improving performance across metrics such as energy savings, water efficiency, CO₂ emissions reduction, improved indoor environmental quality, and resource stewardship. LEED provides building owners, design teams, and operators a concise framework for identifying and implementing practical and measurable green building design, construction, operations and maintenance solutions. Project teams use LEED both as a design guide and verification system to measure progress towards defined performance goals. LEED is structured to encourage interdisciplinary project teams to engage in an integrated project delivery process. By combining mandatory and optional strategies in a framework that rewards successful projects with a third party certification, LEED motivates project teams to take action which results in higher performing buildings.

LEED is structured into a set of prerequisites and credits organised in six key areas namely:-

- Location and transportation
- Sustainable sites
- Water efficiency
- Energy and atmosphere
- Materials and Resources
- Indoor environmental quality

There are a collection of mandatory and optional strategies in each credit category. Mandatory strategies or prerequisites are necessary to qualify for rating. Optional strategies or credits can be selectively attempted and complied with to get to desired level of certification. Four levels of certification are available for LEED rating namely certified, silver, gold and platinum corresponding to 40, 50, 60, 80 points, respectively. Prerequisites do not carry any points.

Allocation of points or relative weightage of points is based on seven impact categories that a LEED project should accomplish. The highest weightage is awarded to credits that address climate change and human health. The impact categories also address issues on protection and restoration of water resources, biodiversity, material resources and including waste, greener economy and quality of life of occupants and visitors (Internal paper on LEED V4: Impact category and point allocation development process by Brendan Owens *et al.*) (Fig. 1).

LEED has now transcended beyond buildings into communities and cities. Quality of life and human experience are central to any city and community. Issues influencing quality of life stretch beyond environmental goals and hence LEED Rating System for cities and communities have a significant focus on equitable education, jobs, prosperity, environmental justices, quality of outdoor air, access to healthy living and food, affordability of housing, avoidance of gentrification, among many other issues.

Genesis of LEED (see “Relevant Websites section”)

With as few as with 19 pilot projects way back in 1998 under its earliest version, LEED has grown immensely, as the economic, human health and environmental benefits of achieving certification have become well known. And the numbers are outstanding.

As of October 2018, total commercial projects participating in LEED are more than 95,600, totaling to total square feet of over 20.59 billion, total certified commercial projects are nearly 44,000 and certified commercial square feet is more than 7.28 billion, residential units (registered and certified) being more than 1.6 million and certified LEED for Neighborhood Development projects totaling at 200. There are more than 201,000 LEED professionals. These numbers demonstrate the phenomenal influence that LEED has had in the green building industry globally in over more than two decades of its inception and existence.

Fig. 1 LEED impact category.

LEED has transcended beyond the commercial office space, the sector in which it originated, with market-specific offerings for schools, healthcare, homes, neighborhood developments, campuses, entire corporate building portfolios and retail settings, acknowledging the unique considerations for each of these space types. LEED has also pushed far beyond new construction projects, its original focus, with LEED for Commercial Interiors, LEED for Core and Shell and LEED for Existing Buildings: Operations and Maintenance, which offers older structures the opportunity to dramatically reduce their environmental impact.

LEED projects can be found in all 50 states of USA and 167 countries and territories, buoyed by local U.S. chapters, the LEED International Roundtable as well as green building councils around the world, united behind the World Green Building Council in a truly global mission.

USGBC also counts nearly 11,000 member organizations representing all their employees among LEED's supporters, including Fortune 500 companies, architecture firms, contractors and builders, product manufacturers, nonprofit organizations, government institutions and many others. These organizations, large and small, represent a broad cross-section of economic and societal interests.

The infographic below provides a snapshot of various milestones in history of LEED, including references to names of "firsts" in key categories of certification (Image courtesy: Neha Koul, Technical Manager, Green Business Certification Institute, India and Mili Majumdar, Author) ([Fig. 2](#)).

Variants in LEED Rating

LEED is a versatile rating system that applies to buildings, spaces communities and cities, both new and existing. Needs and functions of buildings vary based on type of use. There are about 21 adaptations available to suit different building typologies. For example, a hospital building is distinct in use from a school or retail or office building. Although the sustainability framework remains similar irrespective of variations of building functions, credit requirements i.e., technical requirements to meet intent of a specific credit may vary depending of the typology, or number of available points in a credit may vary based on typology or variant. For examples LEED for school encourages community integration through sharing of spaces between the school and surrounding community. This credit on joint use of spaces is specific to LEED for schools. LEED for Buildings is available for both new and existing buildings and the most recent version is *LEED v4.1*. LEED is about leadership and as a rating system, it has set industry benchmarks for high performance buildings. *LEED Zero*, (see "Relevant Websites section") the latest addition to LEED rating thus rewards a complement to LEED that verifies the achievement of net zero goals with *LEED Zero Carbon* recognizing buildings or spaces operating with net zero carbon emissions from energy consumption and occupant transportation to carbon emissions avoided or offset over a period of 12 months or, *LEED Zero resources*:

- *Energy* recognizes buildings or spaces that achieve a source energy use balance of zero over a period of 12 months.
- *Water* recognizes buildings that achieve a potable water use balance of zero over a period of 12 months.
- *Waste* recognizes buildings that achieve GBCI's TRUE Zero Waste certification at the Platinum level.

LEED also has variant for certification of new and existing transit stations, *LEED for Transit*. While the rating system certification of new transit system is modelled after LEED for new construction of buildings, with variations that apply to transit station, LEED for existing transit stations builds on performance of stations tracked through Arc, as its foundation. Measuring performance on critical parameters such as energy used, water consumed, waste generated and diverted, transportation of commuters and quality of indoor environment, on a regular basis provides insight into actual performance of the building and provides opportunity to

Fig. 2 History of LEED and list of firsts.

improve performance on continuous basis. It also allows peer to peer benchmarking and help projects realize tangible savings through retrofits and improvements in operation and management. Powered by Arc, a digital platform to track performance, LEED v4.1 for existing buildings, transit stations, cities and communities provides unique opportunity to measure, track and improve performance and continue to do so over its lifetime.

Cities and communities are very diverse entities with a long life cycle of development and operation. People are central to any city and community and quality of life of residents are very important for a city being recognized as liveable, sustainable and green. *LEED for Cities and Communities* program is developed to revolutionize city planning, development and operations, while also improving life for citizens around the world. In addition to setting credits and technical parameters and policy frameworks for enabling better utilization of energy, water, ecosystems, land, transportation and waste management, this rating system has significant focus of citizens' quality of life. Thus, equity, access, quality of outdoor air, access to education, jobs, poverty reduction, affordability in housing, crime prevention, resilience, environmental justice, healthful food etc., are some critical aspects that have been integrated through appropriate credits in the rating system. Similar to other variants of LEED, performance tracking and monitoring, is central to the system, particularly for existing cities.

Global Rating System

Versatility of LEED in the way it is written and followed has allowed its adoption globally. LEED is the most popular and widely accepted green building rating system and is adopted in over 167 countries, though its origin lies in USA. LEED follows a unique way of measuring greenness or sustainability in projects. Each credit or prerequisite has an intent that defines why a project should meet the intent and the environmental, social and/or economic benefits associated with the intent. The credit defines outcomes that a project needs to derive by following it. Though typically a U.S. code or standard or best practice is referenced, LEED allows international equivalents to be followed to meet the credit intent. Thus, a project gets flexibility to adopt a local code or standard (after due approval from USGBC) without compromising on intent of the credit.

LEED also regularly publishes alternative compliance paths and regional priorities to recognize global best practices, standards and codes. It is thus a flexible and globally applicable system.

Performance Holds the Key

Design and construction of greener and healthier buildings, communities and cities have significantly gained traction over last decades. While design intent can be met through a well-designed green building and its certification, it is critical that these

Fig. 3 Evolution of LEED.

buildings perform as designed. LEED has transformed itself from a purely prescriptive and strategy based system to a performance cum outcome oriented system over the years. The figure below captures the evolution of LEED credit structure in a timeline (Fig. 3).

Performance of any building or any entity is heavily dependent on operation and maintenance and often there is a gap in this area. Green buildings are designed to operate as energy and water efficient buildings with better quality of indoor environment for healthy and productive occupants. However many a times a well-designed green building may fail to operate as a green building, due to lack of maintenance, operational failures and lack of knowledge and understanding over the years.

LEED has evolved itself from a prescriptive and strategy, oriented rating system to strategy and performance driven rating system. With experience from over 94,000 participating projects globally, LEED has gathered immense experience on technologies that work, strategies that are effective, behaviors that can be influenced and failures that are common and avoidable. Every new version of LEED is based on market experience from earlier version and cumulative knowledge sharing by many volunteers and groups of LEED. With launch of the newest version, LEED v4.1 LEED has again raised the bar to increase the impact on our built environment. From improving energy performance to emphasizing human health and integrative building design, LEED is encouraging project teams to operate beyond the status quo. LEED v4.1 is the most inclusive and transparent system to date. It is more inclusive with updated referenced standards and allows projects to earn LEED points through building performance monitoring through use of Arc platform; it continues to drive performance, fully integrating performance outcomes supported by new methodologies and a simple data-driven path so that one can measure performance on an ongoing basis and includes lessons learnt from the market using LEED. The reach of LEED is ever expanding and now also applies to existing buildings, residential projects, transit stations and cities/communities (Fig. 4).

LEED v4.1 for existing entities such as buildings, cities, communities, transit stations is driven by data provided on a digital platform namely Arc. Arc provides a unique platform to track performance of buildings, cities, communities, spaces so that they can perform as designed and set new benchmarks for better performance. The Arc platform was launched in 2016 by Green Business Certification Inc. (GBCI), it helps connecting people all over the world to take appropriate actions and inspire them to make the most informed decisions related to sustainability of our built environment. It is a transformational initiative that has a huge leverage effect on tracking and reducing emissions and other environmental impacts from buildings. It provides the building owner and the building facility manager with a tool to engage with the occupants to create healthier and efficient working and living spaces. It also promotes healthy competition among spaces to raise the bar on performance and set new standards of performance. It thus indirectly promotes newer technology development and helps users to participate in maintaining or betterment of building performance. For example, energy performance in an office space can be improved by regulating thermostat set point, or switching off lights that are not required. Arc helps track both parameters i.e., energy performance and human experience and thus ensuring that thermal or visual comfort is not compromised at the cost of efficiency.

Today more than ever before, the green construction drive depends on technology and data, and the future of green building is concentrated on performance. Powered by Arc, everyone using a space can be involved in its improvement e.g., commercial buildings, residences, retail, hospitals, schools, shopping malls, education institutes, industrial facilities, districts, cities, etc. LEED v4.1 for existing entities leverages heavily on Arc for data tracking and scoring of buildings for certification. For new constructions undergoing LEED certification, projects have to commit to provide data on Arc once they start operations. This shall ensure continuity of performance as promised and committed during certification.

Fig. 4 Performance Tracking Using Arc platform.

LEED and Integrative Design (see “Relevant Websites section”)

Integrative design forms first principles in any design that allows project teams to come together, collaborate and evolve solutions that cut across multiple disciplines. The Integrative Design Process begins at the earliest stages of project planning. It is a collaborative process that focuses on a building’s design, construction, operations and occupancy over its complete life-cycle. The entire team, from client, to architect, to engineering, to landscaping, and so on – identifies goals and establishes performance objectives for the building and its systems during the earliest design stages.

The newest iteration of LEED – LEED v4 and LEED v4.1 – facilitates the Integrative Design Process with an IDP credit requirement. A project attempting to earn this credit must set goals and expectations involving the performance of energy and water systems.

Energy modeling on preliminary base design is done to evaluate advantages of site conditions, all with an eye on HVAC sizing. The impacts of building orientation, and interior and envelope design elements – such as insulation, high-performance glazing, window-to-wall ratios, shading, optimal lighting levels, indoor design temperatures – are collectively and individually assessed in the energy modeling exercise (Fig. 5).

Taking the example of Daikin Industries, Ltd., that has achieved the highest rank of Platinum Certification in the LEED for New Construction (LEED-NC) rating system for the Technology and Innovation Center (hereinafter referred to as “TIC”), in Japan in 2016 has deployed innovative and integrative design methods to arrive at net zero energy consumption. The TIC is a building structure that combines Daikin technologies for achieving a zero energy building (ZEB). Here new energy-saving technologies are constantly being tested and verified with the building serving as a solution model for sustainability. The building uses structural elements as conduits for heating and cooling systems, thus demonstrating principles of integrative design. A combination of passive strategies such as high performance thermal envelope, long and narrow building shape, geothermal energy utilization, outdoor units installed in well-ventilated area thus allowing better heat dissipation and a balanced mix of active technologies such as High-efficiency HVAC, free-cooling HVAC, Glass duct + ventilation system, High-efficiency water-source package HVAC system, Automatic variable-flow water spray system and integration of renewable energy technologies, enabled the building to be net zero, a true leadership level outcome (Fig. 6).

A similar analysis is recommended for water systems. The planned integration of plumbing fixtures, landscaping species, roofing systems, and rain water capture systems can cohesively and efficiently reduce and optimize water use.

Additionally, in the built form there is often a nexus between energy and water systems. For example, a roof garden provides a cooling effect and helps to reduce HVAC loads in hot climates. At the same time, water is required to maintain that roof garden. In the Integrative Design Process, an optimization between energy and water requirements is determined before deciding on final designs for, by way of example, either the roof-garden or the HVAC system.

LEED as a Market Transformative Initiative

LEED is a market transformation initiative. LEED has been instrumental in bringing out critical issues related to buildings and occupants and how building systems and strategies have a large impact on health of people, utilization of resources such as energy

Fig. 5 Team members in integrative design.

Fig. 6 Daikin technology and innovation center, Osaka, Japan. (https://www.daikin.com/press/2016/160908_2/press_20160908_2.pdf).

and water. Energy efficiency in buildings and use of progressive codes and standards to push boundaries in this area has been a significant contribution of LEED. LEED has adopted the ASHRAE 90.1 as the base standard for driving energy efficiency (Fig. 7).

ASHRAE 90.1 has been made more stringent over years and LEED has progressively aligned itself to the latest version. The 2010 version of the standard is over 40% more stringent than the first version of 1975. The stringency is representative of market progression in energy efficiency and evolution of better and energy efficiency technologies, for HVAC, lighting, building insulation and glazing systems among others. The latest version LEED v4.1 references ASHRAE 90.1-2016. Adoption of progressively stringent energy codes as a baseline and making efforts to be better than the code by up to 50%–60% certainly creates great market push on adoption of energy efficient products. There are several markets that have received push due to LEED. Some significant examples

Fig. 7 Energy code stringency progress.

are low VOC paints and finishes, low flow water fixtures, and irrigation devices, controls for systems among others. LEED has also raised awareness on critical health issues such as impact of smoking on health and has introduced mandates on prohibiting smoking in LEED certified projects.

LEED and Human Health

A LEED certified project means a lot: energy efficient and possibly powered by clean and green energy, uses less water, reduced waste, better indoor quality of light, air, acoustics; use of environmentally responsible safer and healthier materials and much more. Human health and well-being has been embedded in LEED from its earliest version. Direct impacts on health and well-being are achieved through credits in indoor environmental quality. Improved daylighting, access to quality views, improved *air quality*, better ventilation strategies, thermal comfort, acoustics, choice of low emitting materials etc. There are several credits that also indirectly contribute to improved health and well-being of occupants e.g., credits on energy and atmosphere that lead to energy savings contribute to emission reduction impacting human health. Use of public transportation and mass transit facilities lower emissions from vehicular sources, which has impact on human health. Likewise, LEED pilot credits on *social equity* address disparities within communities; enables residents with diverse economic backgrounds, age groups etc., to live together; encourage development on site with developmental challenges, all these progressively contributing to social well-being. LEED provides for *mental well-being* through accessibility to open and outdoor spaces, daylighting and enhancing liveability in communities and so on. LEED promotes *fitness* through credits on shared facilities such as gymnasiums or encouraging walking, cycling and non-motorized means of transportation. Issues related to *Toxicity* is addressed through credits on minimizing use of harmful chemicals in building materials, disclosure on human health impacts of products, prohibiting smoking, discouraging use of harmful chemicals on plots and so on (Fig. 8).

LEED for cities and communities have a significant focus on quality of life and address well-being at a larger level as well. Reduction of poverty, access to education and job or healthful food, access to and equitable supply of clean water and power, clean air are addressed through the system to ensure enhanced quality of life for residents.

LEED and Sustainable Development Goals

The 17 sustainable development goals are a call for action by all countries to promote prosperity while protecting the planet. They recognize holistic economic and social progress while tackling climate change and environmental protection. They recognize that ending poverty, and doing so hand in hand with balanced and sustainable development, is crucial to survival of mankind. As a leadership organization, USGBC has been at forefront of meeting Goal 17. By fostering and nurturing several partnerships to realize its global vision on sustainable habitats and buildings, makes USGBC a unique organization. And LEED has been instrumental in contributing to all goals through its credit achievements. A high level correlation between SDGS and LEED credit categories is mapped in the Fig. 9. By way of example, reversing the contribution of buildings to global climate change is a core

Fig. 8 Health impacts of LEED credits. Image Courtesy; Neha Koul, Technical Manager, GBCI, India.

Fig. 9 LEED and sustainable development goals Image Courtesy: Richa Prasad, Technical Specialist, Green Business Certification Institute, India.

goal in LEED. High performing green buildings, particularly LEED certified ones, can significantly reduce greenhouses gases emissions thus directly contributing to achievement of goal 13. This also has highest weightage in LEED followed by weightage on human health that directly contributes to achievement of goal three, good health and well-being.

Examples of Outstanding LEED Certified Projects Globally

CityLife

Milan

Targeting LEED gold

Covering an overall area of 366,000 square meters, CityLife is a new urban renewal project consisting of residences, offices and shopping and has attracted some of the biggest names in architecture such as Zaha Hadid, Daniel Libeskind and Arata Isozaki. Early on, the team behind CityLife conducted a feasibility study of the project. One million Euros, equivalent to 0.07% of the construction cost, was devoted to improve their score to LEED Gold. Another selling point to investors of the project was energy modeling. The model suggested a zero cost improvement, saving 50% of cooling costs (Fig. 10).

Fig. 10 CityLife (Milan).

Vodafone Village

Milan

LEED silver

With 127,000 square meters Vodafone Village is the world's largest LEED for Commercial Interiors certified building and the largest in Italy. Vodafone, one of the world's leading mobile companies with over 406 million global customers, built their new headquarters on an unused industrial area in Milan that has led to the environmental rehabilitation of the site and surrounding area. The roof includes a photovoltaic garden of 800 square meters producing more than 8000 kWh of clean energy every year ([Fig. 11](#)).

Lilla Bommen

Gothenburg, Sweden

LEED for existing buildings: operations and maintenance (gold) Jan 2013

Popularly referred to as L ppstiftet or "Lipstick" because of its red top. History The name Lilla Bommen, or Little Boom, is derived from Gothenburg's proud seafaring history, which dates to the 1600s. Because of its location, on the banks of the G ta River, the city had become a shipping center, with ready access to the Kattegatt, the North Sea, and the Atlantic. For fortification, city leaders constructed high walls and a moat with channels. At the time, those channels were the only passage ways into the city and so, for added security, each channel was equipped with a boom that was lowered at night. In 1989, when Lilla Bommen was completed, there were few tall buildings in Gothenburg. Consequently, it was considered a daring design, albeit one that was tied closely to the city's rich history and current status as Sweden's chief seaport. Most notably, many who have sailed past Lilla Bommen remark that, from the water, it resembles the mast of a ship ([Fig. 12](#)).

Built: 1986–1989 by Skanska Property West AB Purchased: in 2001 by Vasakronan, Sweden's largest property management company Designer: Ralph Erskine, renowned British-Swedish architect LEED Consultant: Piacon, Pia  hrling with sub-consultant ThorntonTomasetti Project Size: 442,160 square feet (41,078.0082 square meters); 22 stories.

Taipei 101

Taipei, Taiwan

LEED for existing buildings: operations and maintenance – platinum certified on July 7, 2011

With 101 floors and nearly 186,000 gross square meters, TAIPEI 101 is one of the tallest buildings in the world. Since its completion in 2004, it has become an icon for Taipei City, Taiwan and has set the quality and performance benchmark for supertall buildings in Asia. From 2008–2010, TAIPEI 101 invested in significant energy efficiency retrofit projects to generate energy and water savings. A review of public lighting was undertaken and resulted in the conversion to more energy efficient luminaires and lighting controls ([Fig. 13](#)). By utilizing Energy Management and Control Systems (EMCS), building managers are able to adjust operating temperatures, modify chiller plant operating schedules and modify chilled water distribution according to actual tenant needs. TAIPEI 101 earned LEED for Existing Buildings: Operations and Maintenance certification and succeeded in:

- Decreasing potable water usage by at least 30% compared to average building consumption
- Saving 28,000,000 L of potable water annually
- Being ranked in the top 30% of high-rise office buildings as benchmarked by the U.S. ENERGY STAR database
- Reducing energy consumption by 33.41 million kWh per year
- Saving more than \$2 million per year

Verdant Place

Shanghai, China

LEED platinum certified

With 22 floors and about 30,000 gross square meters, Verdant Place is one of the landmark buildings in Shanghai city. From 2008–2012, Verdant Place invested in significant energy and water efficiency retrofit projects to achieve energy and water savings.

Fig. 11 Vodafone village (Milan).

Fig. 12 Lilla Bommen (Gothenburg, Sweden).

Fig. 13 Taipei 101 (Taipei City, Taiwan).

The entire existing structural element was kept, but the single panel glass was replaced with double layer laminated low-e glass. The whole, old low-efficient MEP systems (including chiller, pump, fan, boiler, sanitary fixture, lighting fixture, and lift machine) were replaced with new equipment. A review of public lighting was undertaken and resulted in the conversion to more energy efficient luminaires and lighting controls. By utilizing Energy Management and Control Systems (EMCS), building managers are able to adjust operating temperatures, modify chiller plant operating schedules and modify chilled water distribution according to actual tenant needs. Verdant Place succeeded in:

- Decreasing potable water usage by at least 40% compared to average building consumption.
- Saving 2,861,770 L of potable water annually.
- Being ranked in the top 30% of office buildings as benchmarked by the U.S. ENERGY STAR database.
- Reducing energy consumption by 989,839 kWh per year.
- Saving more than \$128,495 per year (USD).

Fig. 14 Hysan place (Hong Kong).

Shanghai Pratt and Whitney Aircraft Engine Maintenance Co., Ltd. (Shanghai engine center)

LEED platinum located in the Qingpu district

The Shanghai Engine Center officially opened in September 2009 as an environmentally friendly and highly efficient CFM56® engine maintenance, repair and overhaul facility. The first LEED Platinum facility in China, the Shanghai Engine Center is a joint venture between China Eastern Airlines and Pratt and Whitney, the latter being a United Technologies Corporation company. The facility incorporates high-performance building solutions from other UTC businesses such as Carrier. Key LEED features at the 26,000 gross square meter facility include:

- At least 12.5% of the facility's energy is being produced from renewable sources such as solar thermal, photovoltaic, wind, geothermal and canal water sources.
- High performance, energy efficient windows contribute to the facility's daylighting system, reducing electricity requirements and the need for additional cooling.
- At least 20% of all construction materials were sourced locally, and 10%–20% of materials contained recycled content. Use of certified stewarded wood products.
- About 70% of construction waste was diverted from landfills.
- Reduced usage of potable water and the construction of a large pond on site capture and stores rain water to meet all sanitary needs

Hysan Place, Hong Kong

LEED platinum

LEED certification has resulted in:

- 22% total energy reduction compared to the ASHRAE 90.1 baseline.
- 30% increase in ventilation rate for the AC system.
- Providing vertical sky gardens that not only reintroduce public green space to residents of Causeway Bay, but also offer light, air, and views not usually available in the region
- A value increase in the entire Causeway Bay portfolio.
- By developing design and operations targets, monitoring changes, reviewing strategies, and reporting progress publicly, we strive to continually improve the firm and increase our positive contribution to the environment through business and design practices that are consistent with our broader social and environmental values, such as future LEED projects (Fig. 14).

Jaypee Vasant Continental Hotel

New Delhi

LEED platinum

The Jaypee Vasant Continental Hotel is strategically located within New Delhi's Diplomatic Enclave. Known for its easy approachability and premium hospitality services, the Continental takes great pride in its many sustainable features and practices. Among them, the hotel recycles 99% of its total solid waste. The project team has managed to reduce the cooling demand by

Fig. 15 Jaypee vasant continental hotel, New Delhi.

having over 75% of the roof area covered with paints having a high Solar Reflective Index. In regard to natural resource conservation, this LEED certified hotel saves approximately INR 7 million in energy and water savings and reclaims 44% of its potable water. Its total GHG reduction is 123 MT of CO₂ (Fig. 15).

**EDS Global
New Delhi
LEED platinum**

Since 2002, the staff and management of Environmental Design Solutions has worked on hundreds of green building projects worldwide. Their deep experience was amply rewarded when EDS pursued LEED Platinum for its New Delhi headquarters. During construction, the project diverted 97% of all waste from landfills, while pursuing high-efficiency performance and superior indoor environmental quality. Important highlights included the installation of three-foot tall windows that spread natural light evenly throughout the open office, thereby promoting visual comfort and occupant well-being. Operational improvements yielded a significant 42% reduction in water consumption, and overall savings of 35% in energy use.

**K. Raheja Corp. Mindspace Buildings No. 5 and 6
Navi Mumbai
LEED gold**

K. Raheja's Mindspace Buildings No. 5 and 6 was built on expansive space and surrounded by 14,000 square feet of professionally landscaped grounds. Its park-like gardens represent nearly 15% of the site's total area. Other sustainable innovations included 100% on-site treatment of wastewater to tertiary standards, allowing reuse for gardening and flushing. Efficiency was a fundamental requirement, and this building produces annual energy savings of INR 34 million and water savings of INR 2.8 million.

**ITC Sankhya Data Center
Bengaluru
LEED v4 platinum**

ITC Sankhya Data Center recently became the world's first data center to earn LEED Platinum, ranking it among the most energy efficient data centers in the world. ITC Sankhya is fully powered by renewable energy. It also incorporates variable capacity technology and a sophisticated sensor network that automatically adjusts cooling, heating, humidification, and dehumidification. The resultant combined energy savings last year were INR 121 million. Other performance highlights include PM10 in the range of 10–20 Ug/m³, Carbon Monoxide below detectable limits, Formaldehyde below 27 ppb, Ozone below detectable limits for most regularly occupied spaces, along with water savings of INR 0.2 million per year.

**Starbucks
Chhatrapati Shivaji International Airport, Terminal 2, Departures Mumbai
LEED silver**

This project is the champion of three prestigious milestones: it's the first LEED-certified Starbucks store in India, it's the 900th LEED-certified Starbucks store overall, and it makes India Starbucks' 20th country with a LEED store. The green features in the store include water efficient plumbing fixtures, energy-efficient appliances and LED lighting that not only reduce the demand on the water supply and energy grid, but help save money over the life of the lease. Integrating sustainable building practices and conserving precious resources is critical as India's population grows. The certification of the first Starbucks store in India represents the company's commitment to conserving resources and green retail but also a strong partnership between Starbucks and Tata.

**Infosys EC-53 Building
Bengaluru
LEED platinum**

Infosys has designed efficient buildings for many years, and they have learned much. The EC-53 Building is one example. It boasts a custom radiant panel-based cooling system that is 30% more efficient than conventional systems. Its building envelope is fully insulated to minimize heat ingress. Over 90% of the occupied space enjoys natural light and outside views. Self-powered,

Fig. 16 Surat city.

Fig. 17 Washington DC.

peel-and stick wireless switches and sensors reclaim energy from the indoor environment. Rainwater harvesting and an onsite sewage treatment plant reduce water consumption. Indoor air quality is continually monitored and balanced at the granular level. These interventions and others cut energy consumption by 42% over baseline, and reduced water use by 50% over LEED requirements.

Surat City

LEED platinum city

Surat city located in Gujarat state of India, with an area of 326 square km and a population of 5.32 million is the first Platinum certified city in Asia. It is the 8th largest and fastest growing city in India and is known for industries such as textile processing, diamond cutting and polishing, petrochemical, thermal power, fertilizer and heavy engineering. Surat has taken crucial initiatives to address the elevation in energy demand due to increase in commercial and industrial activities making it one of the progressive cities in India. These initiatives based on committed target of 10% reduction in energy demand by 2016, entails energy efficiency measures like adopting ESCO model, smart grid application and demand response as well as increase in renewable energy production from solar, wind and biogas. Additionally, Surat has been successful in providing quality water to 96% of the population and treats millions of wastewater to meet water demand in industries and landscaping. The city has also adopted City Resilience Strategy and has been declared as the 4th cleanest city in India ([Fig. 16](#)).

Washington, D.C.

LEED platinum city

Washington, D.C., the U.S capital located in the East Coast expands up to 68.34 square miles with a population of 0.67 million and is the first LEED Platinum city in the world. With its progressive energy goals DC has been able to achieve a reduction of 31.2% by 2013 and aims to achieve 50% reduction in GHG emissions from 2006 levels and 50% renewables in the energy mix by 2032 through wind and solar energy production. DC is also the national leader in green building movement with highest number of square footage per capita of LEED certified buildings. The city has been successful in reducing potable water consumption by

13.5% from 2012 to 2017 and aims at reducing it further by increase in storm water reuse. Waste is well managed in the city with 51% diversion rate from landfill and aggressive strategies in waste reduction such as pricing incentives and ban on plastics. Washington, D.C. has remarkably low per capita vehicle miles travelled and aims to reduce it further through improved public transit systems and safe and secure walking and biking infrastructure (Fig. 17).

Life Cycle Assessment Methods and Procedures and Their Role in Measuring the Sustainability Component of a Construction Technology

Ujjwala Chakradeo and Tarika Mohite Dagadkar, Smt. Manoramabai Mundle College of Architecture, Nagpur, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

The development path that humans have taken, particularly since the Industrial Revolution, has proven to be detrimental to the health of ecological context of the world. The rapid change in the global environment linked to the Industrial Revolution is referred to as global change. Global change is likely to be further accelerated through globalization of the economy. Because of global change, which can be termed as environmental damage, the issues to be resolved are global warming due to greenhouse gas emissions; acidification of soil and water; drastic decline in the quality of air, soil, and water; reckless exploitation of natural resources stored in the soil through mining activities, drastic changes in land-use and land-cover through overexploitation of natural resources leading to desertification of landscapes, associated rapid depletion of biodiversity, etc. All this demands an exploration of a variety of additional pathways for development. There is an increasing awareness worldwide about the state of environment, caused by overexploitation of natural resources for economic development. The issues relevant to conservation of natural resources have to be addressed differently depending upon the ecological, social, economic, and cultural framework in which one is operating. This has led to the evolution of new concepts including that of sustainable development as a basis for overcoming the environmental, social, and economic challenges. Sustainability concerns have gained international acceptance to devise and implement sustainable development policies that can eventually halt and hopefully reverse the effect of global warming.

The term *sustainable* development can be described as enhancing quality of life; and thus, allowing the human beings to live a healthy environment and improve social, economic, and environmental conditions for present and future generations. Improving social, economic, and environmental indicators of sustainable development is drawing attention to the construction industry, which is a globally emerging economic sector and is a highly active industry in both developed and developing countries.

For the construction industry specifically, achieving true sustainability will require a paradigm shift, similar to the one faced by manufacturing industry that strives toward a sustainable approach to development by integrating sustainable strategies at all phases (Vanegas *et al.*, 1995). To overcome the increasing concerns of today's resource depletion and to address environmental considerations in both developing and developed countries, life cycle analysis/assessment (LCA) can be applied to decision making to improve sustainability in the construction industry. This may become possible only when at least some of the stages of that construction technology are quantified to prove its contribution in making that construction technology sustainable. LCA attempts to measure the "cradle to grave" impact on an ecosystem.

Life Cycle Assessment

LCA is a process to evaluate the environmental burdens associated with a product, process, or activity by identifying and *quantifying* energy and materials used and wastes released to the environment; to *assess* the impact of those energy and materials used and releases to the environment; and to identify and *evaluate* opportunities to affect environmental improvements (Asif *et al.*, 2007). The assessment includes the entire life cycle of the product, process, or activity, encompassing extracting and processing raw materials; manufacturing, transportation, and distribution; use, reuse, and maintenance; recycling; and final disposal.

In this study, the LCA is used as a tool to measure the environmental performance of a particular construction technique and to demonstrate the suggestions that can be offered for improvement at each stage in the life cycle of a building.

The LCA caters to the wide array of impact in a stage specific process, where each stage poses an opportunity as well as a constraint to improve the environmental effects. This provides a set of efficient alternatives and qualitative judgment that can help a designer to choose from a range of construction technologies depending on their respective environmental and economic performances. According to ISO 14040, there are four interactive steps necessary for a complete life cycle study: Planning, inventory analysis, impact assessment, and improvement analysis; these are graphically interrelated in Fig. 1. These steps are further elaborated in ISO 14041, 14042, and in 14043 as per Fig. 1.

The first step defines the *goals* and objectives of the LCA framework and its scope (including investigation boundaries or system boundaries). This step establishes a relationship between the purposes of the study, decides boundary conditions of the LCA, and procedure for quality assurance of the study.

The second step is *inventory analysis*. The life cycle inventory (LCI) involves collecting data for each unit process regarding all relevant inputs and outputs of energy and mass flow, as well as data on emissions to air, water, and land. This phase includes calculating both the material and the energy input and output of a building system. It provides a quantitative input/output account of the product or system as shown in Fig. 2.

Fig. 1 Steps for life cycle assessment. *Source:* Authors.

Fig. 2 Life cycle stages, inputs and outputs for life cycle assessment. *Source:* Authors.

Each of these input–output categories comprise of simple materials, specific energy input, or some processes like for kiln burnt brick or cement manufacturing process, which need to be broken down and analyzed in the same way as the main material life cycle process.

The third step is *impact assessment analysis*. It is a quantitative and/or qualitative process to characterize and assess the effects of the environmental burdens quantified in the inventory, the life cycle impact assessment (LCIA) phase evaluates potential environmental impacts and estimates the resources used in the modeled system. This phase consists of three mandatory elements: Selection of impact categories, assignment of LCI results (classifications), and modeling category indicators (characterization). The process may be divided into three steps: Classification, characterization, and valuation. This is to analyze how raw materials used, energy generation, water usage, effluent output, air emission, and solid waste affect the environment.

Finally, the last step of ISO 14040 is the *improvement/interpretation analysis*. This stage identifies significant issues, evaluates findings to reach conclusions, and formulates recommendations. This improvement assessment would allow identification or making changes in the construction life cycle, improving its environmental performance. For example replacing highly processed, nonrenewable resource consumed as building material with renewable resources.

Construction Industry and Environmental Sustainability

The construction industry is one of the largest sectors, which consumes an enormous amount of natural resources, manpower, energy, and money. The process of construction of buildings consumes a huge amount of energy and in turn produces a large volume of GHG. Among the top seven sectors contributing to CO₂ emission in India, the construction sector tops the list with about 17% of the total share, when both direct and indirect emissions are considered (Asif *et al.*, 2007). This emission comes from production and transportation of building materials. Manufactured building materials, which consume a large quantity of energy, are commonly used for building construction. Increased use of these energy intensive materials not only depletes the energy resources, but they also produce adverse environmental effects. The main aim of sustainable construction is to minimize natural resource consumption and also minimize the impacts on ecological systems (Charles, 2013).

In sustainable development discourse, there seems to be general consistency in the presentation of environmental aspects, whereby the environment is viewed both as a *source* and a *sink*. The environment is a source of natural resources. The resources can be categorized into renewal, nonrenewable, and other resources. Renewable resources can be regenerated in a timescale relevant to

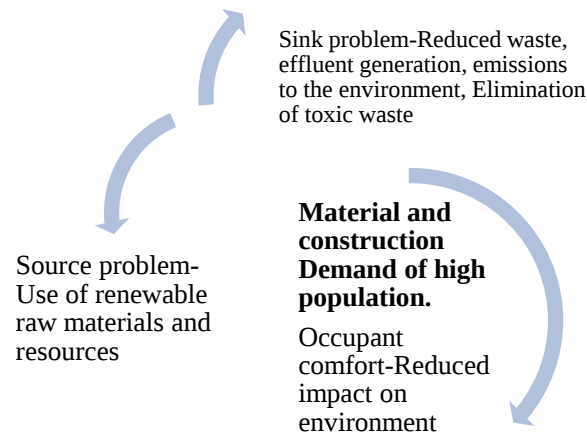

Fig. 3 Environmental Sustainability- 'Source' and 'Sink' side. *Source:* Authors.

man. Nonrenewable resources are those that have taken millions of years to form and can, therefore, not be regenerated on a timescale relevant to man. Other resources include biodiversity, climate (rain, sunshine, wind, etc.), water bodies, landscapes, and terrains. The environment is also a sink for waste resulting from humans and their activities. It absorbs gaseous, liquid, and solid waste as well as the heat resulting from human activity.

Today's increasing demands on environmental resources emanate from high population growth on one hand, and environmentally destructive production and consumption patterns on the other (Meadows *et al.*, 1972). A big population requires more materials from the environment and generates big waste streams. In addition, wasteful production and materialist consumption patterns create a spiraling demand for resources and generate lots of waste. Based on reasonable assumptions about social and a technological condition, the environment imposes limits on economic growth (Gupta, 2008).

Sustainability and its relationship with construction industry considering the environmental dimension of sustainable development is related in Fig. 3.

Construction Technology and Building Life Cycle

Construction technology involves study of the methods of construction to successfully achieve the structural design with recommended specifications. The construction technology entails (1) natural capital: Building materials and water used in construction technique; (2) human capital: Human resource like skilled and unskilled labor; and (3) manufactured capital: Tools and equipment used to execute the technology.

Understanding the sustainability component of any construction technology would involve quantifying, assessing, and evaluating all the aspects of LCA explained above at every stage of construction, such as foundation, superstructure, walls roofs, etc., and interior detailing also. Choices made at every stage offer a plethora of options. The entire spectrum is quite wide and complex. Construction technology involves the choice of building materials and the technique and means used to erect a residential building. Development decisions regarding technology and infrastructure are a major determinant of consumption patterns. It is therefore important to evaluate and make development decisions that structurally contribute to sustainable development. Technologies exist through which substantial reduction in consumption of resources is possible. Efforts to identify, evaluate, introduce, and use these technologies must be made.

This paper demonstrates the possibilities of calculating the sustainability component of wall construction in stone. Basalt stone is locally available in the Vidarbha region and was widely used in rural area of Vidarbha. This technology has its own limitations. It is best suitable for construction of buildings that are not very high, up to three stories, because of its weight. The aim for selecting stone wall construction technology is to demonstrate calculations (partial) for arriving at the sustainable component of this construction technology.

According to Agenda 21 for Sustainable Construction in Developing Countries, "Sustainable construction means that the principles of sustainable development are applied to the comprehensive construction cycle from the extraction and beneficiation of raw materials, through the planning, design and construction of buildings and infrastructure, until their final deconstruction and management of the resultant waste" (Plessis, 2002). The growing significance of the sustainability concept throughout the world has resulted in attitude change in consumption of natural resources for infrastructure development projects. Utilization of large quantity of natural resources for meeting the fast growing building activities and generation of waste has exerted unavoidable pressures on the natural environment with the growing significance in green building concept and the mandatory inclusion evaluation of LCA in building design standards.

By referring to the concept of systems theory, this study proposes that construction technology, when standing in a particular temporal and spatial sequence constitutes the building. The temporal sequence is the requirement that certain activities related to

Fig. 4 Three phases of building life cycle in relation with construction technology. *Source:* Authors.

construction of buildings must be done before others. For example, every building must undergo the following series of stages respectively: (1) raw-material extraction, building material manufacture, assembly on site, use/maintenance, demolition, and disposal/recycling; (2) the spatial aspect is included because of the distance that has to be covered within and between the stages identified above, which involves transport; and (3) onsite, the materials must be placed in certain spatial relationship to each other according to the requirement of the construction techniques to form a building. The discussions are aimed at linking building materials and construction technology to the LCA and environmental sustainability.

The comprehensive construction cycle starts from the process of extraction and beneficiation of the raw materials, through planning, design, and construction on site of building and infrastructure and ends with their final deconstruction and management of final resultant wastes. Thus, the construction process could be divided into three distinct building phases: Prebuilding phase, building phase, and postbuilding phase as shown in Fig. 4.

Prebuilding phase includes manufacturing of raw materials, which includes processes like extraction, transportation of raw material, processing, and packaging. The energy consumed in manufacturing of building material is termed as *embodied energy* of the material. The energy required for transportation of raw material from the production unit to construction site is called as *gray energy*.

Building phase includes execution/installation of construction technology by skilled and unskilled labor using required tools and equipment for the execution/erection process. This phase also includes performance of construction technique during the operational phase when the building is functional or in use. Maintenance of the structure during the use of the built space by the occupancy is included in the building phase.

Postbuilding phase includes demolition of construction technology and disposal of waste generated after dismantling of the built structure. Depending upon the building materials and the composition of building materials used in the construction technique the waste generated can be recycled and reused or biodegraded or dumped in landfills.

Considering these three phases of building life cycle, an environmentally sustainable construction technology can be assessed by applying LCA method. Further part of the study focuses on the LCA of stone masonry, the selected construction technology practiced in the Vidarbha region to demonstrate the possibility of a methodology that can be adopted to showcase the judicious choices so that the construction technology is sustainable.

The Integrated Life Cycle Assessment Applicability to Stone Masonry

The principles of life cycle design provide important guidelines for the selection of construction technology. Each step of the manufacturing process, from gathering raw materials, manufacturing, distribution, and installation on site, to ultimate reuse or disposal, is examined for its environmental impact.

Step 1: Defining System Boundaries

The construction technology selected for application of LCA method is stone masonry as the technology is developed and practiced in the region considering regional constraints and it has strong relevance to vernacular construction technology practiced in Vidarbha region. This study focuses on identified criteria relating with environmental sustainability and construction technology considering the building life cycle.

Step 2: Inventory Analysis

The data and information collected to make an inventory analysis for environmental impact of a construction technology over the life cycle of a building at each stage are (1) material input, (2) energy input required, (3) environmental release and by-product or waste generated, (4) total nonenergy natural resources consumption, and (5) cost input.

Fig. 5 Building life cycle stages criteria with construction technology. *Source:* Authors.

The materials and energy used in construction technology life cycle are organized into three phases: Prebuilding, building, and postbuilding. These stages are parallel to the life cycle phases of the building itself. **Fig. 5** represents the energy and material consumption at different phases by the concerned construction technology.

Further study elaborates the criteria related to stone masonry at the three different building phases. This stage describes the mathematical simulation and presents the quantitative data resulting from the actualization of the calculations. The data for input into the simulations is a combination of empirical findings and relevant literature. To simplify calculations, the wall-strip component is specified as partition wall.

Prebuilding phase

Renewable resources: Basalt stone used in stone masonry is a locally available material at the selected site location. Stones replenish themselves to some extent in natural form and do not have adverse environmental impact. The energy content in processing the stone as building material is lower than that of artificial materials.

Embodied energy of construction technique: The embodied energy or the energy content of a building material comprises of all the energy consumed in acquiring and transforming the raw materials into finished products. It symbolizes the quotient of its environmental friendliness, reflecting the material's closeness to the earth; the more it is refined or processed the more energy it contains, and hence, more environmentally expensive. In this study, embodied energy of construction technique is calculated. Steps to calculate embodied energy of construction technique involves ([Praseeda et al., 2015](#)):

- Identifying the construction technique from various items of work like walling technique, roofing technique, flooring, door window, etc., in the building.
- Calculation of energy value/unit for each item of work based on the material involved and specification.
- Obtaining the total energy value for each item of work.
- The cumulative energy value of all the items.
- Obtaining the energy value/square meter of the construction technique (**Table 1**).

Regional availability of resources: Using locally manufactured products allows significant reduction in transportation (within 100-km delivery radius). Increased use of locally available materials ensures equity in access to environmental resources by all the people as availability of local resources differs according to the topography and climatic conditions. In stone masonry, basalt stone is locally available material within 10-km distance, sand is brought from 50-km distance from selected site and cement from 185 km. The major material used in stone masonry is basalt stone, which is locally available in the region. Secondly, basalt stone masonry is a traditional construction technique used in vernacular architecture and historical structures.

Elimination of toxic waste or by-product pollutant released in the surrounding in manufacturing process of building material: In stone masonry, the building materials used are stone, sand, and cement; cement is the only material that is highly processed but is used

14	CO ₂ emission in kg	Row 9 × Row 12 × Row 13	6.55 kg CO ₂ for 2.5 liter-25 km dist	32.75 kg CO ₂ for 12.5 liter-50 km
	CO₂ emission for materials required for 1 m³ of stone masonry and 5 m² of cement pointing		3.42303 kg	

Note: Method adopted from Shreya, D., 2014. Low Carbon Footprint Homes-Futuristic Homes; Architecture + Design, March 2014, pp. 96–97.

in very small quantity. Stone used for masonry is the least processed material; hence, there is no emission of toxic waste. However the weight of stone is heavy; hence, it impacts the carrying capacity per trip of the vehicle.

Carbon emission due to transportation of building material: Local materials should be used available in the region to reduce carbon emission due to transportation (TERI, 2004). The main benefit of using regional construction techniques is the reduced environmental impact due to shorter distance required for transporting locally available materials. The calculation of carbon emission due to transportation of building materials used in selected construction technology can be done by the method (Sengupta, 2010) given in the Table 2 as shown below for materials used in stone masonry.

Building phase

Technical execution of construction technique

Tools and equipment used for executing the construction technology

In stone masonry, simple tools manually operated and locally manufactured are used in the manufacturing process of building materials as used in construction techniques as well as executing it on site. Simple tools locally manufactured contribute to the

No. of skilled workers – 4; No. of unskilled workers – 12		
Labor for stone masonry: For 1 m ³		
No. of skilled workers – 0.4; No. of unskilled workers – 1.2		

Note: Dutta, B.N., 2016. Calculation of quantity of building material to execute the technique. Estimating and Costing in Civil Engineering (Theory and Practice). New Delhi: UBS Publisher.

economy of the region uplifting the socioeconomic status of the region. This can be achieved because the simple technology-based techniques defining characteristics of local production based on local resources necessarily decentralize the production activity. Decentralized production systems and small scale operations generate local employment.

No. of skilled and unskilled workers used for executing the technique

In stone masonry, the nature of the processes of production and assembly of building materials will also have an impact whereby labor-intensive approaches will generate more employment than capital-intensive methods. The skills required are been readily available in local communities as the material stone has been used since ancient times. **Table 3** gives the quantitative analysis of the number of skilled and unskilled workers required to execute the stone masonry on site.

Water usage

Efficient use of water in construction/low consumption of resource water: In stone masonry, construction requires comparatively less water for execution as well as for curing to reach required strength. This technique uses quarried and seasoned stone with no further processing. This technique uses cement mortar for joint and pointing as finished surface; hence, it needs curing.

Operational building phase: When structure is in use

The check on emission levels of certain building products will reduce the effect on the occupants' health and productivity as well as air quality. In stone masonry no products or materials are used that emit pollutants exceeding the capacity of the building ventilation or filtration equipment to remove them to an acceptable level as the material does not need external finishing coats, such as paints.

Thermal performance of building material: Energy required in building is mostly toward providing thermal comfort. Energy savings in a building can be achieved by appropriate energy efficient design of building envelopes. The building envelope configuration and its thermophysical properties such as heat capacity and thermal diffusivity of the building wall material affect the time lag and decrement factor. Building walls with lower thermal transmittance (U) value has better capability to reduce indoor surface temperature variations (Balaji et al., 2013). Stone wall thickness is more; hence, thermal performance of the technique is better.

Low maintenance requirement: Materials selected to execute the construction technique should respond to the local climatic condition. Secondly, low quality building materials reduce the built structure lifespans and increase the need for maintenance interventions. Stone is intense hard material and its bond with cement-sand mortar is hardwearing and is resistant to damage by abrasion, scratches, or impact. Because of this resistance, the wall is not easily susceptible to damage. For this reason, the stone wall is assessed as having the lowest maintenance requirements. This fact is also proven in the historical structures and vernacular techniques in the region.

Postbuilding phase

Generation of solid waste: Minimal construction waste during installation reduces the need for landfill space and also provides cost savings. The wastage of resources due to inefficient processes or tools causes an increase in investment costs of around 12%. But, beyond the negative influence on costs, wastage also causes negative impacts on resource consumption (Wallbaum et al., 2012). It is observed on site that there is minimum solid waste generated in execution of stone masonry as wet mix mortar is prepared and utilized in proportion per cubic meter masonry to be executed per day on site.

Reusable waste: Material waste generated after demolition of construction technique can be reused as it is without having undergone any type of reprocessing. Reusability is a function of the age and durability of a material. Very durable materials may have many useful years of service left when the building in which they are installed is decommissioned, and may be easily extracted and reinstalled in a new site. When demolished, stone wall can be reused as a building material.

Table 4 Quantified data from inventory analysis used for impact assessment

<i>Environmental impact</i>	<i>Particulars</i>	<i>Quantity</i>	<i>Reference: For 1 m³ stone masonry and 2.5 m² *2 of cement pointing on both sides of masonry</i>
Source side	Stone	1.25 m ³	Building materials for stone wall including cement pointing on both sides
	Cement	0.08 m ³ /117.65 kg	
	Sand	0.440 m ³	
	Skilled workers	0.4	No. of skilled and unskilled workers (Ref. from Table 3)
	Unskilled workers	1.2	
Sink side	Embodied energy of construction technique	883.8 MJ	(Ref. from Table 1)
	Carbon emission due to transportation of building materials	3.42303 kg	(Ref. from Table 2)

Step 3: Impact Assessment Analysis

The third step, impact assessment analysis, is a quantitative and qualitative process to characterize and assess the effects of the environmental burdens quantified in the inventory. More so, the LCIA phase evaluates potential environmental impacts and estimates the resources used in the modeled system. For further analysis the criteria and subcriteria selected for inventory analysis are presented in a hierarchical structure known as value tree, followed by consequential steps such as problem identification, generation of options, assigning relative weights, assessment of consequences, and final decision for impact assessment analysis.

In this study it is categorized on the sink and source side of the environment. On the source side it focuses on consumption of resources and on the sink side it refers to emissions or pollutants released in the environment. The quantified data is used to evaluate environmental impact. CO₂ emissions by use of cement considering the manufacturing process of cement, transportation of raw material, and embodied carbon emission values can be summed and can quantify the contribution to the global warming impact category.

The following table represents the quantity of raw material used in construction of 1cu. m. stone masonry with 2.5 m² wall surface area of wall thickness 0.40 m and cement pointing on both sides of the wall, cost of construction, number of skilled and unskilled workers used in execution of construction technology, embodied energy, and carbon emission due to transportation of building materials. Stone Masonry Results of Mathematical Simulation can be used for impact assessment (Table 4).

Step 4: Improvement/Interpretation Analysis

A simple and effective measure to reduce the environmental impact of construction is responsible materials management at the construction stage. There is, thus, ample scope for energy reduction and carbon dioxide abatement within the construction life cycle. Embodied energy and carbon estimates, of the type provided by the database, are one aspect in the process of evaluating the life-cycle impact of construction. It is also important to evaluate the operational lifetime and maintenance requirements of building materials to enable the construction of true low embodied energy and carbon construction emission. Adopting these simple steps and considering entire building life cycle phases, construction technology selection criteria can be applied at the design phase.

Discussion and Conclusion

Construction technology is the core subject of focus in this study, which has a strong link with sustainable development. This link is explicated by referring to environmental sustainability issues to building life cycle stages of construction technology. This linkage addresses the case in an illuminated manner that the identified criteria are applicable to LCA of construction technology. There is a need to give reasonable rationale for using sustainable construction criteria suited to analyze the construction technology. This paper aims to establish a link between environmental sustainability issues with LCA method as interpreted with building life cycle stages for analysis of construction technology. The link developed so far is used stepwise in LCA of construction technology in the selected site context. Steps, procedures, and precautions to be taken in calculations, related to the LCA of a selected construction technology, are demonstrated in this paper. The same procedure can thus be applied to other elements of building from foundation to roof and also to the finishing materials used in the interiors of the building. Cumulative effect is important. Thus an emphasis is on developing the strategy for calculation at every step of construction and presenting a ready reckoner to the building industry for making judicious choices while undertaking a construction project.

The LCA methodology globally accepted to quantify the multiple criteria existing for evaluating the sustainability of a construction technology is expensive and entails a specific knowledge on this topic, but constitutes the most reliable tool to evaluate the environmental load associated to a construction technology. Consequently, there is a need in the building sector for the classification and characterization of all construction technology employed in a building to prescribe the most suitable construction technique in a selected site context to be incorporated in architectural projects.

Material Culture and Sustainability: Traditional Versus Modern in a Case of Northeast India

Mainak Ghosh and Farha Shermin, Jadavpur University, Kolkata, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

In the past several years, the concept of sustainable architecture has evolved significantly. It cannot be denied that traditional architecture of any region has been a source of knowledge and inspiration in practicing sustainable architecture. Traditional architectural design is an extraordinarily perceptive practice that has evolved through interpretation of past knowledge and experience and has been tailored to meet the needs of time, and this evolution has happened through trial and error without being based on any scientific research or study (Upton, 1993).

Today in the unsustainable world of architecture and planning, we have high regards for sustainability. It is considered as a fresh idea that has made people conscious about concepts of ecology, energy efficiency, cost efficiency, etc. However, we often fail to see that this concept has prevailed throughout the ages and only needs to be understood and rediscovered.

Sustainability – A Traditional Concept

As mentioned before, it is believed that the concept of sustainability is a relatively new idea. The Brundtland Commission's final report, *Our Common Future*, famously defines sustainable development as: "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." Whether we consider this definition or any other and study the traditional architectural and planning practices, the fact would be undeniable that sustainability has been followed as a very important concept in the past.

There is nothing extraordinary in traditional architecture. Traditional architecture and planning has been just a solution to the needs and problems of the society. And these solutions have been a result of years of experience and knowledge. In fact, traditional architecture is not just an individual entity; it always has a particular relationship with the surrounding, as the surrounding environment is also the source of life for all those living there (Oliver, 2006).

The traditional settlements in India have all evolved as a sensitive response to the surrounding, the ecology, climate, and also culture. Spiritual beliefs are another factor that has helped to conserve many natural elements like trees and rivers and water bodies.

For example, in Ladakh, a region in the Indian state of Jammu and Kashmir, which has a cold and dry climate, the traditional houses are built on two levels. The lower level being reserved for cattle, wood, fodder, etc., for winters, whereas the upper level consists of the livable space. Ovens are sometimes placed in the corners, which also help in keeping the interiors warm. The houses are made entirely of mud, sometimes reinforced with horizontal timber members. The sundried brick or rammed earth walls are often mud plastered. The ceiling height is kept low. Thus, every possible care is taken to trap the heat and maintain the temperature inside for comfortable living (Sharma and Sharma, 2016).

Similarly in the hot and dry climate of Jaisalmer of Rajasthan, which is a state in the northwestern part of India, the heat inside the building is controlled by using textures organized at two levels, the town level and the building level. At the town level the buildings are built with unequal heights with parapets and high walls. This creates irregular skylines, which make the buildings shade each other. The roads are also kept narrow so that they are shaded most of the daytime. At the building level, the facades are designed with numerous projections, like *jharokhas*, which are overhanging, semi-enclosed small balconies and *chajjas*, which are small overhangs or canopies over the openings. Such projections not only make the facade visually appealing but also act as a shading device for the facade (Arora, 2018).

Material Culture

"Material culture" refers to the physical or technological aspects of our daily lives, including food items, houses, factories and new materials, etc. Studying the elements of material culture gives us an insight about the people who interacted with or used those objects.

The term *material culture* emphasizes how apparently inanimate things within the environment act on people, and are acted upon by people, for the purposes of carrying out social functions, regulating social relations, and giving symbolic meaning to human activity (Woodward, 2007).

Architecture is a very important element of material culture and also probably the most complex of all. It is also a dynamic component of material culture that should not be studied in isolation from other material assemblages. Thus while studying the architecture of an area, it is very important to understand the preceding social, environmental, and cultural conditions that contributed to the type of architecture in the particular area.

Keeping that in mind when we study the traditional architecture of a place or region, we can see that it connects to every component of the setting very carefully whether it is the surrounding, climate, or culture.

Traditional Architecture in Northeast India

The Northeast of India comprises of eight states, namely Arunachal Pradesh, Assam, Meghalaya, Manipur, Mizoram, Nagaland, Sikkim, and Tripura. This region is very distinct in terms of its customs, rituals, and ethnic culture, which are abundant here. Geographically the region is a combination of plains and mountains both, which makes it abundant in natural resources as well. Most of these states have a humid subtropical climate with hot and humid summers, severe monsoons, and moderate winters. The states of Arunachal Pradesh and Sikkim, however, have a montane ecosystem with cold, snowy winters and mild summers.

The traditional structures are time tested, sustainable, and show great respect to the existing microclimatic conditions and are also sensitive to the natural calamities, including earthquakes and floods, which the Northeast region is extremely prone to.

This region of India is one of the most seismically active regions in the world; three great earthquakes and several big earthquakes have struck this and adjoining regions in the last 110 years. The region experiences severe shaking due to subduction of the Indian plate under the Eurasian plate along the northeastern direction at a rate of about 40 mm per year (Kaushik and Babu, 2009).

The architecture in these areas has developed over the ages as aspects of tradition, climate, topography, and function. Locally available materials like bamboo, cane, mud, and lime are generally used for construction. Influence of the British style has also added to the tradition where bricks, wood, stone, rock slabs, etc., are also being used. As these areas are susceptible to heavy rainfall, sloping roofs are a common architectural feature in all the structures.

Although the traditional architecture in these areas differs from each other as the traditions, culture, and function differ from area to area, there are certain similarities. Based on those similarities the traditional architecture can be categorized in two broad sections: *Kachcha* structures and *pukka* or semi *pukka* structures (Nag and Gondane, 2014).

Kachcha construction

Kachcha, meaning raw or uncooked, is an adjective used for structures made of natural and locally available materials such as mud, bamboo, and thatch. Consolidated earth with timber or bamboo posts are used for the plinth and footing and the walls are made with bamboo frames and mat. The roof is usually thatched with hay, cane, and palm leaves with split bamboo frames. In some regions the walls and floor are also plastered with a mixture of mud and cow dung. In colder areas such as Arunachal Pradesh, the bamboo in the walls is taken over by wood or stone, which helps in retaining the heat.

Similar houses are sometimes built on stilts. Called *Chang ghar* locally (Fig. 1), these stilted houses are built in areas that have high precipitation and moisture content in the soil. The basic idea is to keep away the effects of monsoons. Bamboo being a bad conductor of heat also helps to keep the interior cool in summers and the permeable bamboo surfaces of the walls and floors keep the moisture content low inside (Kaushik and Babu, 2009). The lower level of the *chang ghar* is also used to shelter the cattle, which helps in keeping the interiors warm.

Another variation in *kachcha* structures is the high pitched roof, which is again built with slight variations based on tribal identities. Such structures are mostly built in Nagaland, which is a comparative hilly and colder region. The steep slope of the roof ensures that no water enters the building. The fenestrations are minimal to trap the heat as much as possible (Nag and Gondane, 2014).

Pukka construction

On the other hand the *pukka* or semi-*pukka* structures are made with a combination of organic and inorganic materials. These are a result of the influence of the British colonial architecture to the local architecture.

The most common type of *pukka*, which means cooked or that which is not raw, is the *Ikra* type of construction, which is also known as the Assam type house. Buildings of *Ikra* type of construction are found in most of the northeastern states. The

Fig. 1 A *chang ghar* in a village in Dhemaji district, Assam. Reproduced from Karmakar, S., 2014. Flood control, the missing way – Dispur falls back on 'Coping Practices' of indigenous communities to tackle annual disaster. The telegraph. Available at: https://www.telegraphindia.com/1140717/jsp/northeast/story_18623734.jsp (online) (accessed 16.08.18).

name *Ikra* is derived from the locally available reed known as *Ikra* and it is used extensively in walls and roofs of such houses. Generally, it is a single-story house; however, two-story houses are also found in some places. Based on local requirements, small variations are present in different areas. *Ikra* houses are built on raised plinths to avoid marshy grounds and surface run-off during rains and also stray animals and reptiles. The vertical columns and roof truss are made of wood, usually *Sal* wood.

The wall panels are made of either wood or bamboo frames and are then infilled with the shoots of the *Ikra* reed oriented in the vertical direction; the *Ikra* reed shoots are plastered from either side with mud–dung mixture. In some cases slitted bamboo is also used for the infill instead of *Ikra*.

The covering on the roof truss is a thick stack of *Ikra* reed. However, many such buildings use corrugated GI sheets that are more durable. The roof is pitched with a high gable to cater to the heavy rainfall in the region over many months (Alhasani, 1996). The slope of the roof varies from one-third to one-fifth of the span. Thatched roofs have steeper slopes than the GI sheet roofs.

One major drawback of such construction is the fire hazard. Therefore precautions are taken in terms of design and planning. The kitchen, which is the main source of fire accidents, is built away from the main house or an open veranda of about 3 m is generally provided between the kitchen and the rest of the house to prevent fire accidents.

Ikra-type of construction is not restricted only to dwelling units but also it is implemented in commercial, institutional, and religious structures. The composition of the spaces and also the building elements may differ based on the functional requirements. For example, the shape and slope of roof, windows, doors, etc., for a church will be completely different than a school or college building, and that again will be different from a residential building. Fig 2 is an example of an old institutional building constructed with *ikra* which has survived the tests of time. The architecture follows a general norm of having at least one door in the rear of the house that can act as an escape route in case of any emergency.

This construction technique has been in use for at least 200 years and has proved to be extremely good in several past earthquakes in the region. The lightweight materials used for walls and roofs, flexible connections between the elements, and also the planning are some of the factors that have improved its performance during natural calamities (Kaushik and Babu, 2009).

Sualkuchi – Identifying a Typical Site of Northeast India

Located 36 km away from the city of Guwahati in Assam, is the historic settlement of Sualkuchi. The importance of this settlement throughout history is because of the production of silk and this significance is reflected in the settlement with distinguishing features demonstrating ecological, social, and economic examples for sustainability.

Sualkuchi has been known since the 4th century BCE as a center for silk weaving and is the busiest silk textile center of the northeastern region of India. It used to be a major contributor in the production of the most expensive *Muga* silk. This particular golden silk is a very important part of the Assamese culture. Historically its importance can be determined by the fact that sericulture was exempted from payment of land revenue as the kings of Assam patronized the development of sericulture (Baishya, 2005).

Sualkuchi is a traditional village of weavers, which has preserved, sustained, and transmitted a cultural system. The structure of the heritage settlement as it is today was basically established by Momai Tamuli Barbarua, an administrator of the Ahom kingdom during the reign of Swargadeo Pratap Singha (1603–1641). This patronage led to the advancement and development of sericulture in Assam (Morol, 1979).

The sociocultural institutions like the *Satras* (monasteries), located within played an important role in the survival of the system. This system was sustainable and is reflected in the planning of the settlement as well as in the traditional architecture. The traditional architecture of the settlement had developed as a response to the natural environment and most importantly to

Fig. 2 A more than a century old traditional building of the Cotton College in Guwahati, Assam (Author, 2012. Photograph by Farha Shermin).

accommodate the function of silk production. This sustainable cultural system has not only supported the process of silk weaving but had also led to the advancement of silk production in the region.

Even today, it is sustaining the tradition, although in many cases in a transformed form. This settlement has been chosen because at present it is on the verge of transformation. The settlement is an amalgamation of reminiscence of ancient history and modern culture and thus is a perfect example to study the transformation, which has directly or indirectly affected the aspects of being a sustainable development.

Sualkuchi as a Sustainable Settlement

The historic settlement of Sualkuchi can be explicitly considered as a sustainable one. The concept of sustainability can be defined as having three independent spheres of influence, which are ecological, socioeconomic, and physical sustainability (Tipnis, 2012).

Ecological Sustainability – The setting of Sualkuchi is ecologically very significant. The settlement is located between natural features that form its boundaries, the Bor-beel, which is a wet land, to the northwest, the Gandhmou hills to the east, the river Brahmaputra to the south, and the Siddeshwar hills to the west (Fig. 3). Other than the hills and the water bodies, the settlement lies in a gently sloping land, which slopes down towards the Bor-beel and the river. This ensures good water drainage. The expansion of the settlement is regulated by these natural features.

Also, a small valley is formed between the Siddeshwar hills, which connects the Bor-beel and the Brahmaputra River. A number of manmade ponds are located in this valley. This whole system ensured drainage of the water to the river.

There are number of manmade ponds or *pukhurs* as they are locally called, which act as water reservoirs during dry seasons and also recharge the ground water. The locations of the *pukhurs* were also decided based on the natural drainage. Another interesting feature is the presence of a natural embankment in the east, which benefits a portion of the settlement by obstructing the water and thus preventing the floods. The settlement has restricted its growth towards the river to safeguard the flood plains. The overall ecological setting favors the production of silk.

Socioeconomic Sustainability – A very crucial aspect of sustainability is the social and cultural significance. The local society and culture is best expressed in the way they manage their environment. The built environment in such a sustainable area is thus shaped by the social values and beliefs of the community.

Socioeconomic sustainability in Sualkuchi is prevalent in Sualkuchi from the time it was established. This is evident from the fact that the settlement was deliberately planned on the basis of the communities who were to reside there. Based on oral history and present context, Fig. 4 shows an estimated location of the communities as per the original settlement plan.

The main community was the *Tanti* or weavers' community and the rest were placed to support the Tanti community. The communities were mainly occupation based. They were placed on the site according to hierarchy and also feasibility of workplace. For example, the *Koiborto Para*, which is the fishermen's community, is located near the river bank, whereas the *Mahanta Para*, which is the priest's community, was placed in the heart of the settlement. A water canal was later added, which was not only a source of water but also a physical demarcation that divided the weavers and nonweavers' communities. The same exists even today.

The weavers' communities settled on the west of the canal were very interestingly planned in a grid iron pattern, which formed small clusters. Each cluster is bounded by roads on all four sides. All the houses faced the roads and the central area of the cluster was an open space to grow mulberry trees. The heart of the settlement where the two axial roads meet formed the market place.

Fig. 3 The natural setting of the settlement. Reproduced from Shermin, F., 2017. Impacts of rural tourism on architectural and cultural heritage – The cases of Sualkuchi and Mawlynnong, Northeast India. International Research Journal of Engineering and Technology 4 (11), 318–322. Available at: <https://www.irjet.net/archives/V4/i11/IRJET-V4I1156.pdf> (online) (accessed 10.06.18).

Fig. 5 A traditional house at Sualkuchi. Reproduced from Shermin, F., 2017. Impacts of rural tourism on architectural and cultural heritage – The cases of Sualkuchi and Mawlynnong, Northeast India. International Research Journal of Engineering and Technology 4 (11), 318–322. Available at: <https://www.irjet.net/archives/V4/i11/IRJET-V4I1156.pdf> (online) (accessed 10.06.18).

All the communities were interdependent; the Koiborto community supported by providing fish, which is a staple diet of the region; the *Jalua keot* (net makers) community supported the Koiborto community by providing nets for fishing; the basket makers provided bamboo baskets, which are necessary for rearing of silkworms, and so on.

Further, when we consider a cluster, it has been observed that each cluster functions as an individual unit that combines with other clusters to form a system. This has been discussed later in the article.

The contemplative planning and functioning of the settlement and cluster creates an intricate system that functions as a whole to directly or indirectly sustain silk production. This system also ensured community participation or involvement in the overall process.

Physical Sustainability – Physical sustainability is the most tangible aspect of sustainability. With the change in needs and values of the society, the physical built environment either adapts itself to suit the new demands, is abandoned, neglected, or is replaced. Physical sustainability is that quality of a building that allows it to adapt itself to the changing needs (Tipnis, 2012).

Sualkuchi as a built environment has been growing and developing throughout the ages. Traditional architecture of the settlement is a result of the quality and value that this particular culture has produced. It is typified by durable bamboo framework, and mud plaster. Ikra houses are the common typology seen in the whole of the settlement (Fig. 5). The significance of the architecture has a lot to do with the environment, climate, and weaving other than esthetics.

The ikra houses are generally single dwelling units and do not have common walls with adjacent buildings. The ikra and bamboo construction material keeps the interiors cool in summer and warm in winter and also helps in sustaining during earthquakes. The plinth was constructed in stone or brick. The walls in some of the dwellings were partially constructed in brick, which formed a sturdier base and is extended with bamboo or ikra with mud plaster. The basic structure of the wall is the timber framework. The framework is then filled with ikra and bamboo woven panels. The ikra is cut in size of the panel and laid vertically. Bamboo is used as the horizontal member, which is woven with the ikra. After a few days when the ikra is dry, the wall is plastered on both sides with mud plaster. The finished coat is usually a mix of mud and cow dung, which gives a smooth finish.

The roof can be single or it can be in various levels and multicornered. Initially thatched roofs were used, which were later replaced with corrugated iron sheets.

Weaving, being the main occupation and an important aspect of the culture, plays a dominant role in shaping the architecture of the settlement. Every traditional household has tried to accommodate weaving inside the house.

As most of the communities today have taken up weaving as their means of livelihood, the residential architecture has been altered to accommodate this change in their occupation. The original weavers had a separate area dedicated to weaving inside their house, whereas the residences of those who became weavers later had either an area modified to accommodate the looms or had a separate space outside the house for the same.

As discussed before, a traditional cluster was designed to accommodate the various activities of silk weaving. Similarly, a traditional weaver's house was also designed to accommodate the same. The loom, being the most important element in a weaving room, was the basis of the design of the weaving area. The height of the fenestrations was based on the height of the loom as constant daylight was required for weaving. The weaving rooms had a bamboo *jaali* (latticed screen) running from the sill to lintel level for undisturbed lighting and ventilation throughout the room. The sloping roof is covered mostly with corrugated GI sheet, which helps in easy draining of the rain water but in summer heats up the interiors. This issue is resolved by placing a false ceiling made with woven bamboo mats. Most of these houses also have an attic space, which is the space between the false ceiling, and the sloping roof, which is used as the storage. Fig. 6 shows an illustration of traditional weaver's house and images of a typical false ceiling and access to the attic.

Settlement History and Changes Today

As mentioned before, the settlement was planned during the Ahom rule. But from historic records it is known that the settlement existed since the 4th century BCE on the basis of Kautilya's (a scholar of the Mauryan Empire, who authored the ancient Indian political treatise, the *Arthashastra*) reference to *Suvarnakudya* of ancient *Kamrupa* (historical kingdom of Assam) where the best quality of *patorma* (Pat silk) was produced. The presence of a 400-year-old monastery called as the *Hati Satra* and a temple called as the *Siddeshwar Devalaya*, which is known to have been built in the 14th century BCE by king Arimatta, and several historic manmade water bodies, shows that the earliest existing settlement must have been along the road from Siddeshwar Devalaya. Most of the old buildings are found in and around this area. During the Ahom rule, the settlement became a commercial hub. It was due to this reason the market area gained significance.

The most recent phase, which has drastically changed the settlement, is the construction of the outer road along the Bor-beel, and the Hospital road. These roads gave a new dimension to the settlement, but ignored the natural system of drainage, unlike the historic settlement. There is also an extension towards the east, where new institutional buildings have been constructed (Fig. 8).

Traditional Versus Modern

The new areas along the outer road display a complete different planning and design, which partially or in some cases completely disregards the aspects of sustainability. To understand this, two clusters have been selected for study: One from the historic core and the other from the new developed areas.

Fig. 6 A traditional weaver's house at Sualkuchi. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

Fig. 7 Documentation of a traditional weaver's house at Sualkuchi. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

A traditional cluster

Each cluster functions as an individual unit, which combines with other clusters to form a system. With reference to the Fig. 9, it is clearly seen that the spaces for every activity related to silk weaving are clearly designated. Linear spaces along the roads are used for drying the silk yarn and the finished fabric. The common open spaces bounded by two or more dwellings are used for silk reeling. The weaving of the silk takes place inside the house and the central core of the cluster is used for silk rearing in the mulberry plants. This proximity helped the members to look after the silkworms to ensure their safety from birds and other predators. The clusters were also in close proximity to the market, which enhanced the efficiency of silk production and supply.

The traditional buildings were also designed to be climate responsive and low cost and could sustain natural calamities.

Newly developed cluster

As the settlement expands towards the north, the vernacular character of the clusters changes drastically. Apart from loss of the function of the traditional cluster, a new cluster seems to have developed randomly without any concern to the natural ecology, climate, or even function (Fig. 10).

Fig. 8 Sualkuchi. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

Fig. 9 Traditional clusters. Reproduced from Shermin, F., 2017. Impacts of rural tourism on architectural and cultural heritage – The cases of Sualkuchi and Mawlynnong, Northeast India. *International Research Journal of Engineering and Technology* 4 (11), 318–322. Available at: <https://www.irjet.net/archives/V4/i11/IRJET-V4I1156.pdf> (online) (accessed 10.06.18).

In addition to that, a new typology of residences can be seen in the newly developed areas. This typology is of linear temporary houses for the wage-based workers who work as hired weavers. The linear houses mainly consist of continuous rooms, with each family occupying a room. The standard of living of these people is very low. This has created a social hierarchy in the new clusters that completely disturbs the social sustainability that existed in the past.

The weaving areas are temporary structures made with bamboo with a flat bamboo roof. Fenestrations hardly exist and therefore artificial lighting is required throughout the day. The flat roof, low plinth, and unstable structure disrespect the concept of sustainability in that area.

The other new structures are concrete buildings, which are of two forms. One that follows the traditional vocabulary but uses modern materials like concrete and glass and the other, which is completely a modern structure that is similar to any other building and can exist in any part of the world. The performance of these materials in earthquakes and in maintaining the temperature inside is much less than that of a traditional ikra or bamboo structure.

Fig. 10 Traditional planning vs. modern planning. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

The energy consumption is also considerably high as artificial lighting and ventilation are required. Silk rearing is limited to a few farms, which are not able to fulfill the market demand of Assam silk. The production of Muga silk has reduced considerably, which has not only made it very expensive but has also invited the use of low quality silk from other parts of the world for making the traditional garments.

Findings and Discussion

The study of the settlement of Sualkuchi has been carried out to understand the importance of the relation between material culture and the concept of sustainability with respect to traditional architecture. However, this study inspects a specific type of traditional architecture that is consistently present in most of the areas of Assam, a state in Northeast India. The findings are based on a primary fieldwork conducted in the settlement, which is discussed below.

Sustainable Features of the Traditional Architecture and Planning of Sualkuchi

When the features of the traditional architecture and sustainable design are compared, it is clear that there are several common characteristics in terms of design criteria.

The term *sustainability* may not be known in the history of the settlement but it had been very well manifested in traditional buildings. The natural, economic, and sociocultural conditions of the region have a tremendous influence on the traditional architecture. The settlement planning is an outcome of the physical and environmental factors; the planning of the clusters and the religious architecture is shaped by the social factors and emerging of the temporary bamboo dwellings

is an impact of the economic factors. Also the climatic conditions have very evidently been responsible for shaping the housing as well.

The buildings were designed by their own users and thus the users used all the possibilities and prospects that were offered by their surroundings. They also tried to avoid anything that could make a negative impact in their lives. As a natural result of this process, the traditional buildings incorporated the values of today's concept of sustainability.

Below are two comparative tables showing the materials used in traditional and modern constructions simultaneously, which are listed against the previously discussed three spheres of influence of sustainability – physical sustainability, ecological sustainability, and socioeconomic sustainability (Table 1).

The basic objective of traditional architecture has been to meet the needs through creating simple and functional buildings. Therefore it is very sensible to choose building materials that were readily available in the surroundings, which in this case were mainly bamboo, wood, ikra, and stone (Figs. 11 and 12) (Tables 2 and 3).

From the tables above, it can be clearly concluded that the natural and locally available materials used in traditional construction are much more sustainable than the ones used in modern construction. In terms of today's idea of sustainability, regarding the traditional building culture of Sualkuchi, the following can be observed.

Table 1 Table showing the materials used in traditional constructions

Sl. no.	Architectural components	Materials used	Remarks
1	Foundation	Timber	Locally available and organic though increase in demand can have ecological impacts
2	Plinth	Brick/mud	Locally available bricks and the mud excavated on site for the foundation are used for the plinth
3	Framework	Wood	Wooden framework with bracings supports the structure during earthquakes
4	Walls	Ikra/bamboo/brick	Light weight, low cost and locally available and has insulating properties which keeps the interiors cool in summer and warm in winter
5	Wall finish	Mud plaster with lime wash	Locally available and adds to the insulating properties of bamboo or Ikra
6	Ceiling	Bamboo	Locally available, low cost, and supports local bamboo craftsmen
7	Roof	Clay tiles/thatch	Locally made, low cost, and supports local craftsmen

Fig. 11 Examples of traditional architecture at Sualkuchi. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

Fig. 12 Examples of modern architecture at Sualkuchi. Reproduced from Shermin, F., n.d. Conservation of the Vernacular Residential Architecture of the Historic Crafts Settlement of Sualkuchi. New Delhi: School of Planning and Architecture (Postgraduate in Architecture).

Table 2 Table showing the materials used in modern constructions

Sl. no.	Architectural components	Materials used	Remarks
1	Foundation	Concrete/steel	Durable and allows multiple stories but high cost; materials are not locally available
2	Plinth	Concrete	Faster construction and low maintenance but high cost
3	Framework	Concrete/steel	Faster construction and allows multiple stories but high cost and risky during earthquakes
4	Walls	Brick	Locally made and easily available
5	Wall finish	Cement plaster with synthetic paint	Faster application
6	Ceiling	Plaster of paris/gypsum	Easy and quick installation but high cost and skilled labor required
7	Roof	Concrete/GI sheet	Comparatively low maintenance and high cost but being nonresponsive to Local climate it increases the consumption of energy

Table 3 Table comparing the aspects of sustainability in traditional and modern construction materials

Sl no.	Architectural elements		Ecological sensitivity	Respect for socioeconomic values	Reduction in energy consumption	Response to climate	Local availability	Cost	Supports creative economy	Overall sustainability
1	Foundation	Traditional	Average	Average	High	High	High	Low	Average	High
		Modern	Low	Average	Low	High	Low	Very high	Very low	Low
2	Plinth	Traditional	High	Average	High	High	Very high	Very low	High	High
		Modern	Low	Low	Low	Low	Very high	Very high	Very low	Low
3	Framework	Traditional	Average	Average	Average	Very high	High	Low	Average	Average
		Modern	Low	Low	Very low	Very low	Very low	Very high	Very low	Very low
4	Wall	Traditional	Very high	Very high	Very high	Very high	Very high	Very low	High	Very high
		Modern	Low	Low	Low	Very low	Average	High	Very low	Low
5	Wall finish	Traditional	High	Average	High	High	Very high	Very low	Average	High
		Modern	Low	Low	Very low	Low	Very low	High	Very low	Very low
6	Ceiling	Traditional	Very high	Very high	Very high	Very high	Very high	Very low	Very high	Very high
		Modern	Low	Low	Low	Average	Very low	High	Very low	Low
7	Roof	Traditional	High	High	High	Very high	High	Average	High	High
		Modern	Very low	Low	Very low	Very low	Very low	Very high	Very low	Very low

Sustainable design culture

The designing of enclosed and semienclosed spaces in a dwelling unit was done keeping in mind the function of silk production and the functioning of the cluster as a whole. All these factors not only made an impact on the production of silk but also facilitated interaction among the people. The proficiency in construction methods and materials offers solutions for construction as well as natural disaster issues.

They have efficiently used the natural resources and materials provided by the surroundings and have designed their own environment using local materials to suit their needs, specifically to suit silk production. Thus a building culture very typical to the region has evolved throughout history.

Sustainable land use

The planning and designing of the structures in a traditional historic cluster was done so as to meet the needs of the local weavers. As already discussed before, the other occupation-based communities were made to settle in Sualkuchi to support the weaving community. The planning ensured feasibility and ease of movement of the different communities according to their occupation and thus guaranteeing efficiency.

Instead of treating nature as an obstacle like we do today, they made use of the best out of nature. Measures like avoiding construction along the flood plains and along the natural drainage helped the settlement to check the seasonal floods. Natural water drainage was also made easy by the addition of manmade water bodies. The settlement was also very strategically planned keeping in mind the access routes through land and water.

Designing for durability

The common locally available materials like bamboo may not be as durable as stone or brick but the traditional buildings incorporated suitable protective measures or design features/solutions to prevent damage. Being in an earthquake prone area where safety is the main concern, the lightweight traditional structures serve the purpose very well. However, the important structures like temples and monasteries were built in stone and wood to ensure durability.

Energy efficiency

It is already known that the Ikra and bamboo construction material keeps the interiors cool in summer and warm in winter, which is a necessity for the hot and humid summer months and the harsh winter months in the region. When it comes to silk production, lighting plays the most important role. And as we have seen, the fenestrations were designed to make sure that proper daylight reaches the weaving areas in the structure.

Another factor that makes the settlement energy efficient is the proximity to the workplaces. Locating occupation-based communities close to their place of work, for example fishermen close to the river, and fishnet making close to the fishing community, and also the central location of the market place, made the work-home distances considerably short thus reducing the carbon footprint of the transportation.

Summary of Findings and Discussion

In the past Sualkuchi has evolved in harmony with the surroundings while serving the sole purpose of silk production. The utilization of easily available local materials for construction and the strategic planning serve to support environmental sustainability.

The solutions for disasters, whether it is a natural calamity like flood or earthquake or a fire, have been well thought of, developed, and mastered. The settlement as a whole had achieved not only environmental sustainability but also had directly or indirectly achieved social and economic sustainability. For example the use of local materials by the local people is important in terms of energy efficiency, cost efficiency, and also helps in supporting the local economy.

The enthusiasm with which communities work and support each other to fulfill the objectives of silk production is also an important part of sustainability and that has been possible only through achieving all the factors of sustainability that we have discussed.

Conclusion

This study aimed at investigating and understanding the relation between traditional architecture as a material culture and sustainability. It was also an attempt to determine the potential of traditional architecture in the concept of sustainability today. It has been observed that the main principles of traditional architecture and the basis of sustainability are both in the same track.

Social, economic, and environmental concerns that are the basis of sustainability can be seen in the traditional construction methods and planning of Sualkuchi in the Northeast of India. With this study it has been made quite clear that the local people of the settlement had mindfully taken into consideration the ideas of a sustainable living. The living spaces were designed to improve their lives and enhance the means of their livelihood, which directly or indirectly followed a sustainable design. Today we take sustainability as a solution to the issues we have created where as back then it was a way of life.

The study makes it clear that sustainability has been inbuilt in our culture and recognizing and transferring this knowledge system of the past to the future generations can ensure a more sustainable future.

Retrofitting of Buildings/Built Environment – A Sustainable Development Model

Anjan Mitra and Saptarshi Mitra, The Appropriate Alternative, Kolkata, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

In context of a landscape of growing urbanization, rise of inequity and social injustice, design practices, particularly in the urban realms have taken on an increased value. This value is not only reflective of a drive to create more equitable and just spaces in cities, they also need to be carefully attuned to the nuances of space-making and place-making that learn from and evolve in response to a diverse set of tools, technologies and experiences. Urban design practices thus need to not only respond to complex intersecting needs of various stakeholders, disciplines and methods, but also need to be responsibly spatially grounded in the realities of a particular context (in its social, economic, and political manifestations).

This article attempts to unpack the realities of urbanization and development using India as a symptomatic case of other developing contexts. It elaborates on the overall pattern of development and urban transformation, the polarizing inequalities and the uneven landscape of population concentration to talk about the major challenges and dilemmas that are intrinsically linked to such development. Within this context, it discusses the prevalent notion of sustainable development to foreground the key features that lie at the core of this principle. At this point, the article tries to make a case for expanding the domain of what is meant by sustainable development using cases of realized/idea level retrofitting projects successfully implemented across various scales and typologies of the built environment. The focus on elaboration of actual cases has a twofold purpose. Firstly, it's an attempt to illustrate retrofitting as a spatial concept that at the same time can successfully negotiate complex interlinked spatial-political economies of a particular context. Secondly, it is an attempt at understanding the limits and potentials of retrofitting as a concept that could enable grounded, sustainable, and responsible trajectories of development.

The article concludes with a call for a paradigm shift in the way current spatial practices attempt to fragment and implement projects. In this process, there is an implicit rejection of values of the existing and a rationalization of the economic value as the dominant value. Retrofitting, however, could enable a shift in this thought-action process – one that at its core tries to see a wider gamut of values and assets that are otherwise seen as waste.

Urbanization and Indian Cities – Realities, Policies, Practices

Cities have been seen through multiple lenses from multiple perspectives. They have been seen as agglomeration of global capital (Sassen, 2013), as networks as flows (Castells, 2009), as social space (Lefebvre, 1970/2003), as difference and contestation (Sandercock, 2003; Simone, 2010). They have been characterized according to scale (small, medium, large) and physical features (green, garden, compact, transit, virtual) (see Pacione, 2001). This article does not attempt to privilege one view over another, but rather accept that the city itself is a site of multiple representations, narratives, and actions. Tonkiss (2013) aptly captures this, in saying that “cities are not merely by-products of the operation of capital [...] Cities are the sites of intense struggles between disparate interests and multiple stakeholders, whose ideas, influences and actions together ultimately shape today's urban realities” (p. 24). Cities then have been a subject of various debates, elaborations, and discussions – and have been widely investigated by urban practitioners, economists, sociologists, anthropologists, and ethnographers. They are, in fact, spaces that become places – imbued with a particular character, a particular image (Lynch, 1960). A city is thus shaped, reshaped, and transformed in a continuously temporal process and acts, a la Lefebvre, as a dialectical object – existing both in its image and its materiality. Cities thus become cynosures of people, a collective container that is a manifestation of hopes, dreams, and desires for a better future. Migration to the city-space is therefore an act that is simultaneously physical, aspirational, and political.

Increased migration affects urbanization. The reality is that the human population will be largely concentrated in cities in the near future. Based on 2018 population data, 55% of the world's population is concentrated in urban centers and is projected to grow to 68% by 2050 (UN DESA, 2018). This growth is projected to be concentrated mainly in a few countries in Asia and Africa – such as India, China, and Nigeria. These are fast growing countries, characterized by high population growth, increased urban migration, and high economic growth. India tops these projections, adding approximately 416 million people in its urban centers within these years.

Bhattacharya (2002) discusses the implications of such growth – the rise of mega-cities, issues of urban primacy and sprawl, rise of informality, amongst others. Much of what he discusses holds true today. According to Indian Census Data (2017), India's total population is 1330 million. Of this, 34% is concentrated in 468 (> 100,000 population) urban centers. However, almost a quarter of that number reside in just the top 10 biggest cities. These cities are predominantly of two kinds – the four major metropolises with colonial imprints and the other significant historic urban centers of the country. The explosive growth and urbanization has significant implications for development – provision of civic amenities, infrastructures, services, and shelter in the urban areas (Bhagat, 2011).

What Does It Mean in Reality?

Let us look at the metropolises, which have grown at various times to support the massive influx of people. In Delhi, there has been a physical extension in Dwarka for an intended population of one million residents. Similarly, Mumbai has extended itself into Navi Mumbai. Kolkata too has extended its hinterland and has gone from 100 wards to 144 wards. It subsequently grew into Newtown Rajarhat and virtually has become a large urban metropolitan region. The city has reached a stage where the patterns of physical growth now threaten the East Kolkata Wetlands (The East Kolkata Wetlands were designated as “Wetlands of International Importance” under the RAMSAR Convention on August 19, 2002). In all these cities, the physical boundary extends itself at a high rate. In the process, agricultural lands get converted in real estate; small towns become rural islands in the city, which are subsequently redeveloped; and land is reclaimed from the sea at great cost. New typologies for workplaces, institutions, and housing have emerged, further complexifying the situation. The development of urban areas have thus become a critical management issue.

These sprawling metropolises suffer from an acute scarcity of infrastructure, amenities, and services. There are two major kinds of manifestation. In the peripheries, areas reel from lack of circulation space, services, playgrounds, and community amenities. People improvise and often survive by coping with makeshift infrastructure. On the other hand, are the inner cities. Dating back 200 years or more, these are repositories that hold the uniqueness of the city – its character. The character is derived from the way citizens behave, levels of tolerance, opportunities for all classes of people, etc. These are manifested through spatial arrangements, functional mixes, operational networks, informal networks and many others. However, the intense pressure of development and the high influx of migrants slowly degrade the inner cores into slumlike conditions. Characterized by high density, informal organization, low maintenance, abuse of the built form, poor and unplanned urban services, etc., these areas are ripe for redevelopment. In addition, these areas have higher land value, are heavily contested, and extremely politically active. As the city grows, these areas are often developed through mechanisms that displace – be it the old inhabitants, the existing social structure, lifestyles, built form, ecological balance, environmental quality, etc.

In recent years, various policies and programs have been conceptualized in India to support development. Major critiques of these programs are that they are conceptualized at a scale and translated into siloed projects that they are inherently exclusionary and biased towards a particular form of development. They are also thought to lack nuanced mechanisms for actual implementation and are usually easily co-opted by other intentions during the implementation process. For example – let us take *Pradhanmantri Awas Yojana* (PMAY), which has the promise of providing *Housing for All* in India. [Bhan \(2018\)](#) critiques PMAY from the very basis that should ideally be its foundation and shows that despite best intentions the policy fails to create tangible impact. Even through the Ministry of Housing’s campaign says that “[w]e have constructed 6 million houses under the PMAY,” deeper investigations into the use, the value, and the benefits from these houses are hugely debatable.

Towards Sustainable Development

It needs to be understood that in a country like India, development equates to growth and is often evaluated from the perspective of a single parameter- that of financial profit. This means a focus on quantity over quality, and the prioritization of the most economic methods of production of space, provision of services, and amenities. Consequently large, often-complex urban issues are split to be addressed by a series of different projects – each comfortably couched within a particular discipline. Hence, there are the housing projects, the infrastructure projects, the park projects, and so on. A deeper investigation of the motivations, the benefits, and the stakeholders of the project reveals deep-seated inequalities, and vested interests of a few (powerful) actors as the key driving agenda. For example, [Desai \(2008\)](#) unpacks the Sabarmati Riverfront Development Project to foreground the political and neoliberal intentions that underlie and co-opt what has been discursively described as a project for the city and the people of Ahmedabad.

To facilitate these co-options, the development agenda has adopted a few apparently sustainable buzzwords like *eco-friendly*, *green building*, and *smart cities*. These concepts are usually addressed superficially, and engagement with the urban environment becomes an act of image making. This is possibly the biggest reason behind the reality that while India has continued to develop in a ‘sustainable’ way – actual existing environments, sociospatial practices, cultural diversities, and the built environment in urban areas have been destroyed at an alarming rate.

At this juncture there is a need to critically rethink how urban spatial practices can have more holistic, systemwide impacts. [Jacobs \(2016\)](#) strongly argued for a need to reorient urban renewal practices in context of existing socioeconomic patterns, informal networks and connections, and the implications of their displacement as part of renewal strategies. Only with such perspectives can one start to make cities livable. This can support an essential readjustment of present sustainable development approaches that are predominantly measured through quantitative parameters of efficiency, material use, and techniques to a more qualitative, interdisciplinary, and equitable understanding. [Pacione \(2001\)](#) elaborated such a concept of sustainable development that takes steps to preserve needs and resources for future generations, that propounds fair and equitable use of resources, and that does not shy away from taking responsibility for damage caused due to one’s own activities. At the core of this understanding lies a perspective of viewing resources as collective (space, environment, energy) and of valuing the existing assets of a particular place (economic, material, social, and cultural). Any act of development would thus entail a careful analysis of existing assets, a strategic vision for qualitative improvement of the system, and careful implementation of the vision through evolved, context-specific spatial practices that understand, prioritize and negotiate trade-offs.

Retrofitting – A Concept

This article discusses an expanded understanding of retrofitting as a possible concept to further sustainable development trajectories.

Retrofitting has been broadly understood to be the process of critical replacement/addition of components to an existing system. It has been widely used in the fields of manufacturing, environmental management, etc. It has also been used in the fields related to the built environment such as sustainable architecture and conservation (Paradis, 2016; Dave and Prasad, 2010). In these contexts, retrofitting has generally been employed as a method of engagement with the existing – a process that maximizes efficiency and resource utilization. That itself makes use of this method extremely relevant to spatial practices in the urban Indian context – which is replete with extensive preexisting built form, especially in the urban cores. The method of retrofitting is essentially nonstandard, based on a keen awareness of existing assets, resources and a comprehension of their value. The approach concentrates on reduction of waste wherever possible by using appropriate design strategies. In this sense, the first step to retrofitting can be compared to a medical diagnosis of a patient. The process acknowledges that that total systems rarely collapse as a whole; rather some of its components fail to meet the required needs or performance standards and can be addressed as such. It also operates with an understanding that the built environment and buildings are dynamic systems that are capable of adapting and adjusting to the changed circumstances, albeit up to a limit. With new inputs over time, this system might be stressed/destabilized – preventing optimal performance. Retrofitting engages in holistic diagnostic and strategic interventions within the existing system (in this case the built environment) – and can potentially enable value added interventions that would not have been otherwise possible if the method started with a rejection of the existing assets and values.

An even further expansion is an awareness that ‘value’ could be aspects of the system that are invisible upon cursory diagnosis. In engaging with the built environment, the most apparent asset of value is the building. But concurrently, there exists a whole other set of values: Social, cultural, lived experiences, collective memories, lifestyles, heritage, skills or occupations, natural resources etc. The sum total of all these values is a truer representation of the system – and not just the economic or the material value of the tangible assets. If retrofitting is engagement based on existing values, it becomes a much more powerful concept if employed from this perspective. In this form, it becomes a concept – a search for a context specific spatially grounded and appropriate solution that is also inclusive, responsible, smart, green, and sustainable.

Retrofitting could thus enable a shift in the thought-action process behind sustainable development – a concept that tries to see and respond to a wider gamut of values and assets that are otherwise either invisible or seen as waste. As a concept, its applicability is expanded to wider contexts. It essentially becomes an analytical approach to understanding and responding to urban issues and is versatile enough to be adopted at various scales – from that of a city to a neighborhood, a building, or an institution, to the microscale of private residences. Even if employed as a concept, retrofitting in the domain of the built environment must have the following two characteristics. Firstly, it must be extremely rooted to the particularities of a system. The methodology of engagement and implementation must not be prescriptive or generic, but a product of a thorough diagnostic of the system. Secondly, the strategies must be spatially grounded in the place, as only then can there be lasting tangible impact. As such the implementation could take up various forms, such as but not limited to restoration, conservation, revitalization, infill development, etc.

The authors have been engaged in several cases where they have tried to practically implement this concept of retrofitting as a possible trajectory towards sustainable spatially grounded urban practice. The following section elaborates a few demonstrations, across scales and types.

Case 1: Retrofitting a traditional residential typology in North Kolkata.

This case is that of a house, located at *Durgacharan Mitra Street* in *Darjeepara*, a traditional neighborhood in North Kolkata. Dating to almost 300 years, this house is characteristic of the typical residential typology in the old core of Kolkata. The existing house had a partially open to sky inner space with other spaces arranged around it. It's a three-story load-bearing brick structure with a narrow brick staircase for access. The floors have also been constructed in the traditional system using the *Kari-Bargah* (beam and rafter) technique, over which there are two layers of terracotta tiles and lime concrete. The house had the old wooden louver windows, cast iron railings, and other finishes and materials that had aged gracefully. Over time, a separate toilet block was added into this space, and the kitchen occupied part of the verandah. The house had a 300-year-old family deity of *Radha-Krishna*. There were regular religious ceremonies, and this was an actual matter of pride for the family (Figs. 1 and 2).

The owner of the house is a retired life insurance agent and lives with his son on the premises. The family have been long-term residents in the same location and as such, the owner has built up an intimate wider social network in the neighborhood. Apart from the owner, parts of the house were being used by other entities. The ground floor was used by the local club, and there was a small daily needs shop on the porch of the house. The family was in significant financial hardship, which prompted the owner to think about his home as a financial asset (Fig. 3).

Due to a strong social link to his neighborhood, the owner did not want to adopt the standardized practice adopted by homeowners in such cases, which is to outsource the (re)development of the premise to a private developer (*promoter*). In this arrangement, the promoter funds the development of the property, and the owner provides the lands. In return, the owner gets a share of the new built-up area as compensation. After project completion, the owner is free to continue staying in his share of area in the new building, or free to relocate and sell this area for financial gain. Because the model is driven primarily by financial gain (from the promoter's perspective), such redevelopment has a lot of issues. Almost always, the old building is torn down to make space for a new one – as this process is apparently easier. The agreements in terms of benefits always tend to be skewed in favor of the promoter. The project timeline is usually very short (as the promoter also needs to compensate the owners for accommodation

Fig. 1 Ground floor plan I before.

Fig. 2 The building I before.

Fig. 3 Internal condition I before.

during the project) and the quality of construction is also questionable. Also, these new constructions in the old neighborhoods tend to be architecturally incongruous insertions in terms of typology, materials, and treatment.

The initial hesitation of the owner prompted him to engage us in the project. Primarily we tried to figure out an alternative development model following the concept of retrofitting for this project, in which we tried to prioritize the following factors: The owner would not have to forgo his ownership, he would get major benefits from the (re)development, there would be financial benefits, he would retain his existing social networks and the family deity would still remain in the same premises. For us, the most practical and plausible solution lay in the realization that the building structure was in good condition, with minor typological shifts, and conservation and reorganization of the built form could accommodate all these requirements.

Our strategy was to retain most of the original structure and strategically add vertical access and services. With these additions the building was converted into three self-contained double-bedroom apartment units with services and infrastructure matching levels of new construction. Moreover, these apartments retained the feel and flavor of the old spaces and enjoyed all its built-in advantages – high ceilings, larger space, good natural ventilation, connection to the street, etc. A small addition on the roof was conceptualized as a permanent temple that could house the family deity, and also accommodate daily rituals and practices. A small niche was even conceptualized on the ground floor where the preexisting shop still functions (Fig. 4).

To make the entire implementation process cost effective and compatible with the existing, the project stressed reusing old materials, sourcing materials from second-hand markets, recycling available materials on site, etc. Added to the fact that we newly built very little, this significantly affected final costs which were approximately half of the cost of standardized construction. Furthermore, we avoided creation of much demolition waste, minimized the embodied energy of our intervention and ensured that the (re)developed building integrated seamlessly into the neighboring context. Finally, there was careful project management and planning to ensure that the implementation was done in a way that the owners could still remain on the premises during the entire period.

The conserved building opened up alternative trajectories to financial stability for the family. Being essentially three self-contained units, the owner was free to rent or sell two and still keep staying on the premises. In the end, he kept the first floor and sold the other two. Compared with a promoter driven process, all the gains from the sale were his, which made the project financially successful. It has been 10 years since this project, and the building has had a new lease on life that is at the same time safe, comfortable, and congruous with its surroundings. But we believe that the real gain is also in the fact that the project did not disrupt but in fact strengthened a 300-year-old social network while at the same time minimized environmental damage and destruction. This model of retrofitting to facilitate a sensitive development approach is time consuming and takes a lot more effort – mainly because it is a process of inclusive and negotiated spatial practice. In this process it is important to build on trust and value, and practitioners need to go beyond norms of formal engagement as dictated by terms of professional consultancy.

Fig. 4 Transformed floor plan.

But the benefits are many, specifically in terms of a trajectory of development that is not just environmentally but socially sustainable (Figs. 5–8).

Case 2: Transforming an old tannery in Chinatown into a sustainable enterprise.

The case is located in *Tangra*, in the eastern part of Kolkata. *Tangra* was historically developed by the Chinese community who migrated here in the 19th century, and the area gradually became the Chinatown of Kolkata. Chinatown subsequently grew to become an integral part of Kolkata city's cultural heritage with a different ethos, and set of social and cultural values.

The area had a concentration of tanneries and a host of small industries and services like carpentry workshops, beauticians, etc. The dominant typology of the area has uniquely developed to suit the requirements of tanning, featuring large span structures that have residential spaces, storage spaces, and a variety of workspaces. These spaces usually occupy huge footprints. However, the West Bengal Government has given orders to move all the tanneries from the city to the outskirts and suburban regions to reduce environmental pollution. This led to a sudden emptying out of the tanneries and the displacement of workplaces for the resident Chinese population. Physically, a number of physical structures and warehouses were left in an empty and abandoned state. The process also led to fragmentation of the social structure of the local Chinese population who eventually sought to shift their base to other places. The future of Chinatown in Kolkata has become a serious urban concern from financial, environmental, and social terms.

Fig. 5 Internal stair using wood and cast iron | after.

Fig. 6 Transformed building.

Current developments in the area have been those of high-rise residential gated communities that cause large-scale displacement and change the landscape of the entire neighborhood. It was within this context that we collaborated with i-LEAD (an educational institution based in Chinatown) to revitalize a part of Chinatown through the redevelopment of an old, vacant tannery warehouse. For us, the key assets in the place were its historic associations with the Chinese community, the unique small businesses, and the characteristic architectural typology comprised of different scales and volumes. We also identified the gaps in

Fig. 7 Transformed building within the urban fabric.

Fig. 8 The proud owner I after rehabilitation.

the sociospatial fabric in the neighborhood: The huge percentage of built-up and the lack of open public spaces, and the void in work-related opportunities for the local residents (Figs. 9 and 10).

Developing an architectural program was a key task for this case. This was done in a collaborative manner, keeping in mind that different stakeholders had different needs and priorities. There were three major stakeholder groups – the institute (iLEAD), the people from Chinatown who would study/work at this institute, and the wider community. The final program was derived from a mix of the needs of these stakeholders and of an analysis of the existing spatial conditions in and around the warehouse. There were three major components that capitalized on existing assets, values, and demands in the area: entrepreneurship development, education, and skill development spaces; small business opportunity spaces; and community spaces. These took various forms, such as a training center, a school, a skill development center, a bakery, a beauty parlor, rooftop open public spaces, etc. (Figs. 11 and 12).

Fig. 9 Old tannery building | before.

Fig. 10 Ad-hoc developments over the period | interior volume.

The program had to then be integrated within the building in a sensitive way. As with other cases, we adopted an approach of minimal intervention, frugality of material use, and recycled, repurposed, and upcycled products. The multiplicity of programs with their own specific needs fit perfectly in the existing tannery, which had different scales and volumes of space to begin with. However, some practical spatial reconfigurations were needed to further increase space use efficiency. In one area, a combination of structural steel inserts with prefabricated papercrete (wastepaper mixed with cement) was used to create an intermediate floor. Services such as fire, security, accessibility systems, and PHE systems were inserted into the building to make it fit for use in its new purpose. As far as possible, waste and scrap material were repurposed in their original configurations – and design was used as a tool to integrate these within the space. For example, thermocol from packing crates was repurposed as false ceiling panels, tires were repurposed as swings, plastic bottles as vertical planters. All these small elements work to humanize the environment, and soften the harshness of the existing building (**Fig. 13**).

As clear from the description, retrofitting and use of appropriate techniques made the process of repurposing of the tannery much less expensive (in terms of finance, embodied energy, material use, etc.). In addition, the tannery now has created several spaces that have the potential to connect to the wider neighborhood – directly and indirectly. The open-air rooftop sports complex and the multipurpose hall and food court are valuable facilities for the neighborhood, which has otherwise no access to open spaces. These spaces are made to be accessed and used by the community free of any cost or condition. The beauty parlor, bakery, and the utility store employ and also serve the local community in addition to students of the institute. A large number of tannery workers and other kids from the hinterlands are either students or enrolled in the institute's skill development or entrepreneurial training programs. Together, all these activities make the institute a thriving, vibrant place that is at the same time extremely grounded in the sociospatial realities of Chinatown (**Fig. 14**).

Retrofitting here is both spatial as well as programmatic – and addresses sustainability from varying perspectives. However, this was only made possible through the collaborative effort of a willing and passionate investor, who believes that a good business must also have aspects of social and environmental equity for it to become sustainable.

Fig. 11 Transformed tannery and the street.

Fig. 12 Transformed interior space.

Case 3: Retrofitting (Revitalization) of a popular sacred cultural destination: Kalighat Temple Precinct.

The Kalighat temple is a prominent sacred and cultural destination of Kolkata. Kalighat predates the history of Kolkata itself, and is influential in shaping development of the city. It is almost 400 years old and is the most important sacred site beside the Adi Ganga River (now named Tolly's Nullah) (Fig. 15). As such, it occupies a key position in the Bengal mindscape. The complexity of the built/natural fabric, the multitude of stakeholders, and its long history make Kalighat a politically and culturally sensitive historic area. The temple itself has an area of only 16,000 square feet (out of which 80% is built) but caters to an average of 30,000 visitors daily. On special days, this number can reach 100,000. This places extreme stress on the temple and its hinterland, making it vulnerable in terms of safety, security, and environmental quality. In 2013 the High Court passed an order for safety and security of the pilgrims visiting the Temple as well as its environmental improvement (Fig. 16).

Fig. 13 Meaningful reuse of waste.

Fig. 14 Community facility, sports center on the roof of the tannery.

Fig. 15 Kalighat | historic image.

To respond to the High Court order and also the growing development needs of this precinct, Chief Minister of West Bengal Mamata Banerjee initiated the Beautification of the Kalighat Temple Area project. She appointed the Kolkata Municipal Corporation (KMC) to coordinate the entire process. Subsequently, the KMC formed a project monitoring committee involving the Mayor, KMC, KMDA, MLA, MP, local councilors, police, traffic, and local stakeholders. The purpose of this committee was to oversee the entire process. Based on our previous experience with conservation and cultural tourism, the KMC appointed us to the project as architects/development consultants.

We started with a diagnostic assessment of the area, traced daily established practices and interviewed stakeholders to foreground their emotions and concerns. This went hand in hand with an assessment of environmental issues, livelihoods, pilgrim facilities, the local economy and the *dala* shops (ritualistic ingredient shops), legal complications, etc. We looked at historical references to trace morphological transformation, tried to understand the importance of Kalighat as a *Sati-Peeth* according to

Fig. 16 Kundapukur, Kalighat historic image.

Fig. 17 Proposed image of revitalised Kalighat precinct.

Hindu mythology, studied Kalighat *pata* – the indigenous craft, the sacred rituals of the temple, temple management practices and its economy, associated roles of *sebait* families (groups responsible for overseeing management). What we realized is that there are several layers of complexities that involve a wide range of stakeholders that manifest in this space, coupled with an overwhelming daily influx of people. We realized that waste disposal is a serious issue, and that Kalighat is an environmental hotspot due to regular flooding of the Adi Ganga that inundates a large part of the precinct (Fig. 17).

The exercise led to a belief that instead of beautification what Kalighat needs is an inclusive planning exercise to come up with strategies for a negotiated development of the area. This would be akin to what Patrick Geddes suggested as ‘conservative surgery’ – small changes in the sociospatial context that ultimately create a cascading effect of structural change in the area. Moreover, in light of the existing complexity, these small solutions cannot be imposed but need to evolve from the area itself. The first step to a workable inclusive solution lies in expanding the scope of the project from the temple precinct to a larger hinterland – the *Kalikhsetra*. This can be then followed by the collaborative enactment of certain strategic planning provisions. We identified certain thrust areas for intervention, as below.

The first set of interventions concern the temple precinct and its immediate surroundings and linkages, including the *dala* shops, which are essentially in encroached spaces within and outside the temple complex (Fig. 18). They make the area congested, unsafe and insecure. At the same time, these shops are an essential component of the sacred rituals and the core of everyday traditional practices. The system has been operational for generations, providing livelihoods for *sebait* families and direct dependents associated with the temple. The High Court ruling categorically mentions that the temple be cleared of such obstructions and alternate provisions for their rehabilitation be created in an amicable manner. In addition, as the temple has grown, so have the requirements of space. The temple area is restricted and inadequate for carrying out sacred rituals and daily activities. There is a general lack of public space and the *Bhog* kitchen and allied services are too small to sustain the activities. Furthermore, certain activities, such as the ritualistic sacrifice of animals on auspicious days, create hazardous waste, and there is at present no safe way to dispose of such waste. All these issues necessitated major structural and service reorganization of the temple – conceptualized as a series of collaborative, negotiated implementation strategies.

Another layer of interventions were conceptualized that address the larger scale of the precinct and its links to the socio-economic structures. This relates to the informal networks around the precinct and the large number of poor, specially abled people who flock here in hopes of alms and charitable donations. It addresses issues of legibility, ease of movement and access for both vehicles and pedestrians in the area. Finally, it tries to respond to the historic cultural landscape links of Kalighat and Adi Ganga. This is conceptualized in the form of a religious circumambulatory route (*parikrama*) around the area that sanctifies and

Fig. 18 Kalighat temple at present.

Fig. 19 Joint survey plan of the existing precinct submitted to the High Court.

restores the foreground of the temple. Together, these interventions are aimed at strengthening the resilience, robustness, and efficiency of the precinct while at the same time acknowledging its histories and collective memory.

In both these cases, the idea of retrofitting played a central role. It was an important concept that helped us design the strategic interventions that added on and strengthened the existing sociospatial networks. It was also the main method of engagement. This is because the precinct has a high heritage value, complex legalities and ownership issues and is extremely politically charged. Furthermore, new land for construction is virtually unavailable and even public land is difficult to reclaim without mass evictions and displacement. Retrofitting here gave us a unique trajectory of thought-action to negotiate these potential challenges.

We put these across to the monitoring committee in the form of a preliminary revitalization plan for the area. The approach in the form of a revitalization plan has been appreciated. The public departments tactically wanted to break the project down into

Fig. 20 Revitalization scheme.

Fig. 21 Proposed view of the revitalised Kalighat temple.

phases, and resolved to tackle the first set of issues in Phase I. This also ensured that the project would comply with the directives of the High Court order.

The main strategies for this phase involved rehabilitation of *dala* shops, increase in temple precinct space, and adequate service upgradation. Planning for this stage has been initiated by identifying the exact number of *dala* shops affected and their sizes and types for the purpose of relocation and reorganization. To address the issue of space the strategy adopted would be to group the available temple land along with the intervening public space (that of the adjacent Kundapukur, which was originally connected to the temple as per our historic research). This would provide much needed relief within the temple and generate additional areas that could be retrofitted to make room for service upgradations. The proposed temple would be made safe and secure with proper delineations, access points, and crowd management mechanisms. Once this idea was presented to the stakeholder groups, all groups understood the potential benefits and accepted the suggestion (Figs. 19 and 20).

Fig. 22 Design development involving local craftspeople and stakeholders.

Having established the main temple area, we concentrated on an appropriate rehabilitation strategy for the *dala* shop owners. This was accompanied at all stages by conversations, discussions, and negotiations with the beneficiaries. The focus was on fairness and a uniform shop module was designed based on the average existing footprint. It was then checked for workability through multiple consultations with the users. Some compromises were made to improve safety, such as absence of kitchens in the relocated shops to reduce fire hazard. To eliminate any kind of preferential bias it was decided that the reorganized shops would be allotted on the basis of a common public lottery. Approval was obtained from the stakeholders in a final joint meeting, which was held in presence of the administrators and local public representatives. There was universal acceptance, and this document has been submitted to the High Court and has been endorsed for working out an immediate action plan.

The proposed first phase interventions have been agreed to by KMC, local councilors, stakeholders, and even political leaders. This is because the strategy took the path of least resistance between varied interests in a process of negotiated coproduction. In a historic area loaded with complex sociocultural and political issues, this project validates retrofitting as a sustainable development approach even within a largely conventional planning setup, creating a strong substrate of interaction, collaboration, and agreements between entities that oftentimes are at odds and have confrontational stances. This maximizes the probabilities of sustained and continued efforts towards developing the precinct following a development trajectory that is sociospatially inclusive and sustainable (Fig. 21).

Case 4: A strategy to sustain an orphanage through community based tourism.

This is a case that has its roots in the Incredible India campaign promoted by the Ministry of Tourism, Government of India and supported by United Nations Development Program. The campaign is basically a community-based tourism initiative, where the unique experiences of living with and within a community are shared with tourists who are looking for an immersive travel experience in the country. This is done by developing appropriate hardware (tourism infrastructure) through sensitive architectural and design inputs and matching software (capacity building, management, and operation) through local NGOs/CBOs having exposure in the community building and tourism sector. As part of this campaign, we were involved in a community based rural tourism project in Mukutmanipur, Bankura, West Bengal, where we worked with a like-minded partner NGO.

We got an opportunity to get engaged in this project when we met with Antodaya Ashram (an orphanage) in the village Paoshi in Paschim Medinipur, West Bengal. This orphanage was going through a period of extreme financial liability and was finding it difficult to sustain itself. However, it was a valuable institution in the village and hosted almost 60 girls of various age groups. Apart from being a significant institution in the area, their other asset was that they owned ample land, picturesquely situated at

Fig. 23 Local skills and craftsmanship using locally sourced traditional materials.

Fig. 24 Multipurpose space for dining and activities in an improvised vernacular setting.

the bend of the Orissa-Bengal tidal canal. Our engagement with the situation was to find an appropriate strategy to add to the existing sociocultural linkages that the ashram already had with the local community, while at the same time find a way to alleviate the ashram's lack of assured financial capability to keep doing their work effectively.

The resultant conceptualization – *Mon Chasha* (Cultivator of Mind) – has been conceived as a tripartite arrangement comprising of a design partner, a tourism partner, and a community partner. The mechanism we designed borrowed from our experience of similar development processes during the Incredible India campaign. *Mon Chasha* was imagined as a community-led tourism initiative that highlighted and intimately curated the rural Bengal experience. As such, *Mon Chasha* is a process – the beginning of which is spread across a two-acre parcel of land. The process began with developing the right hardware (accommodation, facilities, etc.) and appropriate supporting software (cultivation of local skills, curation of myths, and an authentic Bengali cuisine).

Fig. 25 Improved typology to suit the rural Bengal context.

Fig. 26 Appropriate interiors involving local materials and skills.

Fig. 27 Evolved cultural space.

Since the focus was on promoting rural experience, the required hardware was conceptualized in a way that is essentially local (Fig. 22). The process started with the identification of a critical mass- the minimum facilities and amenities that needed to be built, and the quality of space that was necessary to sustain and support the other activities. Imagined as a space that is quintessentially rural Bengal, the architectural program started with four cottages (for four people each) with attached services and enough add-on spaces where people can relax, interact, and engage with each other. In addition, there was a decision to create a multifunctional community space in the form of a *Baithak* (lounge), a dining space, and a kitchen (Figs. 23–26). While the programming was important, its translation in terms of materials, techniques, and detailing was equally important. The architectural style was thus derived out of traditional skills and constructed using local skills and materials such as bamboo, thatch, *tal*,

Fig. 28 Authentic traditional Bengali cuisine | intangible heritage of rural Bengal.

Fig. 29 Rural craft and interpretation center.

Fig. 30 A traditional rural Bengal experience.

hogla, etc. The Chang typology was adopted as a base reference, as it is seen in similar climatic conditions, is efficient in using passive methods to increase user comfort and uses similar material and skill palates. However, modern materials have been adopted as they are practical, for example, in the toilets and sanitary fittings. The whole intervention also has systems of gray water management, waste recycling, etc., to minimize the environmental footprint.

Added to the hardware is the software, at whose core lies the ethos of Mon Chasha. It is a place where waste segregation and recycling are part of everyday practice. There is a deep-seated engagement with the natural cycles – ingredients for food is sourced from seasonal vegetables and locally grown produce. The community in the village have also been engaged with the place – in not only working at Mon Chasha, but in taking tourists around, showcasing their crafts, conducting boat trips, and performing in the evenings. There are certain implicit codes of conduct here, which have an uncanny way of making sense even to first time visitors (Figs. 27 and 28).

The space and the relationships have evolved, even transformed over time. Mon Chasha was meant to be an insertion into an existing sociocultural network to strengthen it, but in some ways, it has also started making its own sociocultural networks – with the ashram, the village, and the myriad tourists that come here. This network is ever increasing. The space has also evolved to have a richer experience – the campus now has a *goshala* (cow-shed), a *khamar* (granary), workspaces for local crafts, a sacred space for rituals, vegetable gardens, decks, a pond, and many others.

Being a process, we would like to believe that there is no definitive end. However, the process started from very humble beginnings, from financial paucity and a lack of any definitive idea. The implementation process was phased keeping in mind two things. One was the very low capital cost for the first intervention, and the second was building in periodic maintenance, additions, and alterations so that there are periodic opportunities to engage with the surrounding community. Mon Chasha has been running for six years now. It has approximately 85% occupancy and enjoys a unique position as one of the six must-see tourism projects of West Bengal.

The place has helped in sponsoring the Ashram for their activities and has also enhanced village livelihoods. In addition, it has become a landmark space of the surrounding areas. We believe that behind all these successes was the key idea of building onto and maximizing the existing value of a system – in this case the unique relationship of the ashram and the village, available land, picturesque settings, and ample local skills. Retrofitting in this process started not in the spatial realm, but in figuring out strategic interventions within the existing sociocultural milieu. It was then necessary to follow up the thought with an appropriate and nuanced spatial manifestation.

Mon Chasha is thus essentially different than a conventional tourism resort in an idyllic destination, in the way it is conceived, built, operated, and managed. It is a development process that is collaborative, coproduced, and inclusive. It's a process that is financially viable, yet at no point considers that as the only value. That is the reason it grows – naturally, efficiently, and inclusively. This nuanced natural growth is the real proof of its long-term sustainability (Figs. 29 and 30).

It is important to note that even though the above process showcases a trajectory towards sustainable spatial interventions, one needs to understand that the case is extremely specific and dependent on multiple factors, which is a major limitation. A process like this needs a collaboration between stakeholders with implicit trust, sensibility, and sensitivity to comprehend contexts holistically. It also needs a diverse range of expertise, skills, and capacities for implementation. This makes such processes difficult to replicate or scale.

Conclusion

The case of retrofitting a traditional house engaged not only with the conservation of a heritage residence but also the owner's struggle with growing financial pressure, compromised lifestyles and fear of disconnect from his existing social network. Where traditional spatial practices saw his heritage as a liability that is best demolished, the trajectories adopted showcase how it in fact has created additional financial and social security and has improved his quality of life.

In the revitalization of the old tannery, the key challenge was that an urban typology with strong cultural and occupational roots was suddenly perceived as useless, wasted space that was ill-suited to positive transformation within the overall planning and development framework of the city. The adoption of retrofitting as the process was able to transform this discarded space into something that created new community space in the neighborhood, strong bonds with the local community and trained and prepared future generations to successfully cope with the loss of the traditional occupations in the areas. The process has even created ripple effects of positive change through its indirect influence in the area.

In the case of the redevelopment of the Kalighat temple precinct, retrofitting has enabled an essential reframing of a beautification project with a short-term public (political) agenda into a case of negotiated development grounded in traditional practices, wisdom and collective memory. This has also led to equally grounded spatial solutions that successfully negotiate the complex morphology of spaces, activities, environment, safety, and security to suggest a development alternative that has been deemed viable and has been agreed to by all stakeholders. Furthermore, the process has, for the first time, been able to bring together different stakeholders at the same table. Together, these create a sociospatial context that has an increased probability of being holistically sustainable in the long run.

While the above approaches have a strong existing base scenario, the case of Mon Chasha delves in explorations at a different scale. Here, the intervention can be seen as the retrofitting of an existing structural relationship between different actors in a context, using space, design, and mutual dependencies to kickstart processes of positive change. This process foregrounds several values and experiences as assets, such as traditional wisdom, tangible and intangible unique experiences, available skills, passion, etc. These values are at the core around which is created an authentic experience of rural Bengal that at the same time is firmly grounded in the realities of Paoshi and the Antodaya Ashram. This process is able to highlight shared memories, lived experiences, disappearing crafts, and dialogs that are lost in current urbanization and development trends. In the process there are benefits that are accrued to all stakeholders: Sponsorship to the Ashram, work for local villagers, a secure future for kids, revenue for the resort and so on. These closed loop cycles and holistic dependencies make this whole exercise sustainable.

In summary, the cases illustrate the myriad contexts, issues, challenges and trajectories involved in the practical application of retrofitting, as both a concept and an idea to shape development projects. In each case, retrofitting creates a more holistic understanding and opens up alternative trajectories of design and implementation that are otherwise difficult in traditional forms of spatial practices. It also enhances the flexibility and effectiveness of the engagement to achieve positive change and adds value to

an existing circumstance. These interventions are at an appropriate scale, spatially grounded, and socioculturally relevant. The approach acknowledges the value of the existing (economic, physical, social, cultural, tangible, intangible, natural, etc.) and reinterprets them in an appropriate way so that they become more meaningful. The process looks at finding solutions that start from an immersion within an existing scenario and a natural process of evolution leading to appropriate trajectories of action. At its core, these trajectories reframe different forms of unacknowledged, unrealized, wasted assets into mechanisms that add value to the existing system in a collaborative, coproduced method that cuts across domains of conventional disciplines.

These examples illustrate the wider need for transformation of thought that drive current development attitudes. This needs to percolate and create a paradigmatic shift in the way spatial practices currently implements a wider development vision as a collection of fragmented, siloed, unidirectional projects. Only then can one move past the current conceptualization of sustainable development as efficient growth into something that can go beyond buzzwords to imagine a vision for the future that values the existing assets, is people-centered, inclusive, just, and equitable. Sustainable development would mean more than quantitative growth – it would mean qualitative betterment of human life in a responsible way, for now and for the future.

Roof Gardens to Vertical Farming

Abraham George, Indian Institute of Technology Kharagpur, India

© 2020 Elsevier Inc. All rights reserved.

Introduction to the Development of Roof Gardens

Gardens are more than intrinsically related to mankind and an early reference can be found in the Bible in the story of creation in *Genesis the Garden of Eden in Genesis 2:8* (Bible, 1989). The reference to a garden, indeed roof garden or a terrace garden, could be traced back to the Hanging Gardens of Babylonia, which was built by King Nebuchadnezzar, who ruled Babylon for 43 years starting in 605 BCE. The Hanging Gardens consisted of vaulted terraces raised one above another, resting on cube-shaped pillars and the hollows filled with earth to allow trees of the largest size to be planted. The pillars, the vaults, and terraces are constructed of baked brick and asphalt. The existing oldest and best-preserved roof garden is from the Renaissance, located in the town of Pienza in Sienna, Italy. On the roof, a formal garden was erected for Aeneas Silvius Piccolomini to hold audiences. Now it is a UNESCO World Heritage site and its palace has remained virtually untouched since the 15th century.

In the modern era, roof gardens developed into social hubs for the public. Prior to the advent of air conditioning in the 19th century, they were a choice way to cool off in the evenings. The Casino Theater was the first theater to be completely electrified when it opened in 1882; however, the biggest draw was not the bright lights, but rather the roof garden theater. It quickly became the people's choicest destination during hot summer nights, which set off a roof garden craze in Manhattan and nationwide. At a time when most theaters were forced to close down for the summer due to the heat, these open-air theaters performed successfully to offer comfort and kept the businesses going.

In today's context, rooftop garden increases the percentage of greenery in built-up urban areas and brings back the vanishing urban green space; other than that, there are other benefits such as environmental, esthetics, social, and economic benefits. Added greenery in a cityscape also performs as the lungs of the city, cleaning off the carbon dioxide and illness-causing dust from the city atmosphere. Further, it contributes heavily to reduce the urban heat island effect and the related discomfort. From the behavioral point of view, these green spaces are also shaded and offer cooled space within the city's hot environment, furthering human interaction and livability. It retains and manages storm water, improves air quality, modifies urban microclimate, and creates biodiversity. Green roofs modify building behavior in terms of solar radiation, external temperature, relative humidity, and winds. These factors are slowed down and reduced as they pass through the foliage that covers the roof.

Developers are often held back from including rooftop gardens in their designs mainly due to concerns like high initial cost, chemical resistance of roof concrete to chemicals, and structural loading capacity. Lower initial cost solution is not the cost-effective alternative in a normal rooftop garden, since the resulting consequences become unbearable at a later date. A higher first cost and appropriate solution may be thus justified many times over for a durable product with minimal maintenance. Green roofs generally have longer life than exposed roofs because the additional layers of substrata and vegetation act as protection for the roof membrane. Other economic benefits include increased property values, increased marketability of a property, and opportunity to assist in LEED and GRIHA certification in several functional categories.

Design Principles

Design of rooftop gardens or its various types as discussed primarily depends on the investment potential of the developer or owner. However, in any form rooftop gardens offer a multitude of benefits including comfort and pleasing environments to avoid boredom. If one does not intend to invest higher initial costs, then it is advisable to go for planters, grow bags, and containers that are made of high grade plastic. This reduces the loading and water requirements when combined with drip irrigation. A plastic house or shade house as appropriate to the climatic context enables the plants to thrive in any season. The intent of the rooftop design must be clearly specified also the context in which the design is made to stand. Plants in containers offer better chances for relocation and differing mix patterns. On the other hand fixed rooftop gardens neither offer varying mix nor freedom from heavy maintenance and repair if not done for appropriate load bearing, chemical effects resulting from fertilizers, and corrosion due to dampness. Designing a rooftop garden for floriculture is advisable, since it brings a bit of return on investment.

Design is not restricted to genius, nor is it a uniform or simple process, nor is it distinct from practicality or detail. Practicing designers are aware of its convolutions, but they also half believe in the lightning flash (Lynch and Hack, 1984). The method's influence on the design should match the design intent (Jones, 1992). Understanding the methods in the design process allows a landscape architect to evaluate the end result of his or her design and to quickly construct changes in the design by applying different methods. Balcony and façade gardens with mulch, getting ready for planting, and how to integrate the horizontal and vertical landscapes are shown in Figs. 1 and 2 respectively. Planters in balcony gardens,

Fig. 1 Balcony and façade gardens with mulch, getting ready for planting, Wailea Marriot, Maui, Hawaii. *Source:* Prof. Abraham George.

Fig. 2 Balcony and façade gardens: Integration of horizontal and vertical landscapes, Wailea Marriot, Maui, Hawaii. *Source:* Prof. Abraham George.

indicating the importance of size of plant to pot and space, are shown in [Fig. 3](#). One must be careful to choose and maintain proportions in this case. Balcony and pathways gardens and integration of horizontal and vertical landscapes are best explained in [Fig. 4](#). While the penetrating light and water are most important, one must be careful to keep water from passages as it might lead to aquaplating and accidents to the splashing of water on surfaces like corridor floor. The same in principle is to be observed in placing water fountains and jets of water in landscaping. Roof gardens ensure protection from solar radiation and improve environmental esthetics by integration of plants with the right proportions, color, texture, and branching habits as illustrated in [Fig. 5](#). Organization of plants with their soft features and color and texture celebrates a built structure, as illustrated in [Fig. 6](#). These examples are a few eye openers to the value of rooftop and terrace landscapes if designed and maintained properly. Design is often guided by heuristic reasoning involving solution images, analogies, or restricted sets of form-giving rules that partially and provisionally define the solution for a problem; that is, what it should be like ([Rowe, 1982](#)). This approach is from an architect's perspective where forms of reasoning are analogous to Lynch and Hack's methods.

Vertical Farming

A swift turn to rooftop gardens is happening in today's world as the population explosion due to increased longevity has brought serious problems to the nation, particularly regarding the elderly. As people age their mobility declines, which leads to declined social interaction, activity, dignity, and self-respect. Urbanization with vertical housing blocks also poses a threat to the aging society because land and environment is a major concern in the urban environment, so too safety and security. Wellbeing, which is a measure of mental and physical health, will decline with aging. Environmental concerns, including issues of ecological justice, sustainability, and a focus on issues of food and security have also increased. Hence a community incorporating vertical farming

Fig. 5 Roof gardens: Protection from solar radiation and improved aesthetics by integration, Wailea Marriot, Maui, Hawaii. *Source:* Prof. Abraham George.

Fig. 6 Seasons depicted in pathways gardens: Integration of horizontal and vertical landscapes, Wailea Marriot, Maui, Hawaii. *Source:* Prof. Abraham George.

will enhance the wellbeing of the elderly with additional engagement and the pleasure of being with nature, which adds to the participation of the elderly in sustainability of urban agriculture, which adds to their value (Fig. 7).

Relevance of Vertical Farming

The significant increase in urban population will have greater impact on the availability of food, engagement of free time with nature, and participation of producing daily use vegetables for the elderly. This impact is due to shrinkage of arable land as a result of urban development and the lack of time and resources, along with weakening of the bond among family members in terms of nuclear families and pressures of job and work environments. One major solution to prevent this shrinkage is the high-density development that is now practiced all over the world with its own associated problems and advantages, such as vertical farming. The amount of arable land per capita has decreased from 5100 m² in 1950 to estimated 1600 m² in 2050. An estimated 10⁹ ha of more land will be needed for cultivation, if traditional farming practices are to continue as they are practiced. In India, changes in rain patterns and temperature could diminish its agricultural output by 30% by the end of the century. To overcome the scarcity of land and to maintain the constant productivity in urban area, vertical farming is to be incorporated into the vertical housing blocks of the contemporary world, which also can be seen as a viable solution for the engagement and participation of elderly and increasing their self-worth (Sashi Bhusan Raut, Research Scholar, Dept of Architecture and Regional Planning, IIT Kharagpur under the guidance of Prof. Abraham George). A comparison of soil-based versus soil-less agriculture is shown in Table 1, while the technologies employed in vertical farming are given in Fig. 8.

Fig. 7 Tomatoes growing in soil and Swiss chard growing in a soil-less system. *Source:* Public domain: <http://www.fao.org/3/a-i4021e/i4021e06.pdf>.

Table 1 Soil-based vs. soil-less agriculture

Category		Soil-based agriculture	Soil-less agriculture
Production	Production quality	Depends on management and soil characteristics. Cannot be fully controlled because of exposure to natural environments.	Fully controlled by appropriate use of nutrients at different stages of plant growth and creation of artificial environment suitable for plant growth.
	Yield	Not constant because of soil characteristics and management.	Constant because free from soil and varies by management practice.
	Sanitation	Unhealthy condition because of water being contaminated by use of fertilizer and pesticides.	Healthy condition because of minimal risk of contamination of water.
Nutrition	Nutrient delivery	Cannot be controlled at the root zone because of soil characteristics and structure.	Fully controlled at the root zone because of soil-less water medium.
	Efficiency of nutrient use	High loss of nutrients due to leaching and runoff.	Much less loss of nutrients because of uniform and real time adjustable flow of nutrients.
Water use	System efficiency	Maximum loss of water due to soil characteristics.	Efficient use of water by the help of sensors. Less labor cost for watering.
	Salinity	Water becomes more saline and requires large amount of water to make it usable.	Saline water can be used. Also requires large amount of water when dilution is required.
Management	Labor and equipment	Less investment because of standard machines. More manpower needed for operations.	High investment in equipment and high initial set up cost. Less manual labor required for operation.

Fig. 8 Technology associated with vertical farming. *Source:* Prof. Abraham George.

Conclusion

Rooftop gardens are an enchanting design opportunity combined with energy efficiency and a welcome design solution to enhance coherence of urban life and enhancement of property value. Vertical farming is a method to increase physical participation, psychological benefits, and social cohesiveness among elderly, which in turn enhances their self-worth and wellbeing. It is one of the sustainable methods of food production and lends a feel of involvement in making one's own food. Vertical farms are easy to

maintain, convenient to harvest, and keep the pollution at lower levels. The elderly feel connected with their families, friends, and neighbors not only at the social level but also at the environmental level and can improve their quality of life. To fulfill these objectives, we need to develop the models, methods, and systems of vertical farming at affordable limits. The immediate attention shall be focused on urban multistoried housing and other amenities.

Study of Junctions With Bamboo: An Attempt Towards Their Classification

Rajarshi Ray and Parthasarathi Mukhopadhyay, Department of Architecture, Town and Regional Planning, Indian Institute of Engineering Science and Technology, Shibpur, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Bamboo has been used in construction for ages; however, the practice has been primarily artisanal. The engineered material for similar construction practices has been timber. As awareness increases about the environment, engineers and technologists look for sustainable construction materials, alternative to timber, where bamboo stands out as a forerunner. [Mukhopadhyay and Dutta \(2015\)](#) states the following major advantages of using this natural construction material.

- Bamboo take about 3–5 years to mature whereas timber take about 15–25 years.
- It produces 35% more O₂ than equivalent stands of trees.
- Some species of bamboo sequester up to 12 metric tons of CO₂ from air per hectare.
- Bamboo forestry assists in soil conservation, watershed development, and wasteland reclamation.
- Its fibrous morphology and natural lightness helps bamboo structures to absorb more strain energy released during earthquakes than timber.

However, bamboo has a few disadvantages for which it is not used as widely as timber. One of the major reasons is its geometry, which imposes certain restrictions on the workability; this restriction is essentially experienced while designing junctions with bamboo. Less availability of data about strength properties of different bamboo species that are deemed fit for building construction, is another limitation. These are some of the key reasons for which use of bamboo has remained, by and large, traditional. Amidst this, sustainability of bamboo has created interest regarding this building material beyond its traditional users, among architects and designers. Subsequent experimentation has resulted in attempts towards improved practices in bamboo junctions.

Need for Documenting Bamboo Junctions

Junctions in bamboo structures are at the interphase of different structural members and they play the important role of effectively transferring force between members, and to achieve continuity between elements with controlled displacements. This load includes self-weight of the structures, the external forces acting on them, and various internal and external stresses due to changes in temperature and humidity. In response to different structural challenges, a number of unique bamboo junctions have been innovated. The design solutions have generally been arrived at, through trial and error; and they are rather specific as opposed to being general. Lack of documentation of these solutions along with limited scope of communication between design-innovators, artisanal or otherwise, have led to the creation of unstructured knowledge, which has a lesser probability of getting re-used.

This article, therefore, attempts to classify the standard bamboo junctions to help their utilization and application for constructions which are yet to come. This would also encourage and initiate dialog between architects and designers from various places to take the work ahead in utilizing this sustainable building material.

Classification of Bamboo Junctions

Observations of bamboo at junctions of different building elements, like roofs, walls etc., reveal varied application of bamboo. One would observe that both whole bamboo and split bamboo pieces have been used in traditional, as well as, in improved practices of fabrication of junctions. Occasionally the constituent member elements of a bamboo junction are observed to be in the same plane, and sometimes they are skewed. Again, the method of jointing varies considerably in each of the above mentioned cases. Based on these observations, an attempt has been made in the following sub-sections to classify bamboo junctions into four main heads. The sub-sections investigate and illustrate these four core types through examples.

- (1) Shape and form of structural members,
- (2) Level of technology applied,
- (3) Planarity of the structural members, and
- (4) Method of jointing.

Shape and Form of Structural Members

Round or whole bamboo culms ([Fig. 1\(a\)](#)) are typically tubular hollow cylinders, which are longer than their diameter. For different construction purposes, the whole bamboo pieces are slit along their vertical axis to produce split bamboo pieces

Fig. 1 Classification of bamboo based on shape and form: (a) round or whole bamboo, and split bamboo; (b) bamboo column made of combination of whole and split bamboo. Reproduced from (a) Janssen, J.J.A., 1981. *Bamboo in Building Structures*. Eindhoven: Eindhoven University of Technology.

(Fig. 1(a)). In fact, there has been contradictory claims regarding strength of whole and split bamboo pieces. Whereas National Building Code (NBC) of India (BIS, 2016) states “strength of split bamboo is more than that of round bamboo”, Mukhopadhyay and Dutta (2015) reports that round specimens of the species *Bambusa balcooa* are stronger than their split counterparts. They explained their finding by the fact that donut geometry of hollow round specimens provides it with enough section modulus to offer more moment of resistance than the solid split ones. In practice, combination of whole and split bamboo pieces are used (Fig. 1(b)). Thus, based on shape and form of constituent members, bamboo junctions may be classified into:

- Round or whole bamboo junctions,
- Split bamboo junctions, and
- Round-split junctions.

Level of Technology Applied

Based on the level of technology applied, bamboo junctions may be classified into two broad types:

- Low-tech bamboo junctions, and
- Hi-tech bamboo junctions.

The traditional junctions with bamboo, which are simple, inexpensive and fabricated with easy-to-obtain technology, are commonly referred to as low technology junctions or abbreviated as low-tech junctions (Fig. 2). The simple methods of fabrication may refer to tying with ropes or nailing together. Low-tech junctions can be easily comprehended, free from specialization, and can typically be fabricated with a minimum of capital investment. Because of their ease of construction, these are simple to construct and does not involve much of a technical input. They are rather products of human intuition and common sense.

The use of bamboo, as an alternative to timber, of late, has spread beyond low-tech genre. Different architects and designers have adopted the approach of combining other engineered materials with bamboo to solve specific design needs. In the given example (Fig. 3), bamboo has undergone a formal treatment process and the assembly is a calculated engineered approach. Such junctions and assembly are, therefore, complex and involve a high level of technology. High technology, abbreviated as hi-tech, is conceptually opposite to low-tech, intrinsically non-traditional and innovative.

Planarity of the Structural Members

During fabrication of bamboo structures, it is observed that constituent members require to be joined together to create a framework or a structure. The members may lie in the same plane or in different planes. Variation in planarity of the structural members

Fig. 2 Typical low-tech bamboo junctions: (a) full-lapped joint; (b) half-lapped joint; (c) spliced joint with inserts; (d) saddle joint with lashing; (e) gusset-plated joint; (f) simple bolted connection with mild-steel washers. Reproduced from Bureau of Indian Standards (BIS), 2016. Part 6: Structural Design, Section 3, Timber and Bamboo. New Delhi: BIS.

Fig. 3 Example of a hi-tech bamboo junction. Reproduced from Yu, X., 2007. *Bamboo: Structure and Culture – Utilizing Bamboo in the Industrial Context with Reference to its Structural and Cultural Dimensions*. Essen: University of Duisburg-Essen.

of a bamboo junction causes variation in the bending moment generated at that junction. Based on the planarity of the bamboo structures, they may be classified as:

- Coplanar bamboo junctions, and
- Non-coplanar bamboo junctions.

In order to appreciate a coplanar bamboo junction, one may consider a rectangular frame-work fabricated using four pieces of bamboo lying in the same plane; again, sometimes a diagonal member is added as a cross-bracing to strengthen the frame-work. Another example of coplanar bamboo junction has been illustrated in [Fig. 4\(a\)](#) where six bamboo members, lying in the same plane, are bolted to a circular ring. [Fig. 4\(b\)](#) illustrates a classic example of non-coplanar bamboo junctions, where a number of small triangular bamboo pyramids have been joined together forming a bigger one.

Method of Jointing

Any and all of the above mentioned three types of bamboo junctions and their sub-classes employ different methods of jointing and fastening, which are specific to the specific application. The end goal is to retain the pieces in their desired or predicted positions. The popular methods used for fastening and joining bamboo members are as follows:

- Use of ropes,
- Use of bolts and nuts,

Fig. 4 Planarity of bamboo junctions: (a) several bamboo members in the same plane forming a coplanar junction; (b) Casalini's Cultural Pyramid, Lago Trasimeno, Italy by Antoon Versteegde – an example of use of several non-planar junctions in a bamboo structure. Fig. 5 Bamboo junctions using ropes. Reproduced from Larry, 2010. Bamboo construction from big bambu on met rooftop. Available at: <https://www.flickr.com/photos/muyyum/4850823894>.

- Use of plates,
- Use of carpentry joints,
- Use of glue.

Use of ropes

Tying with a rope is a simple mechanism that does not require much of engineering knowledge (Fig. 5). However, the choice of the material of the rope and the kind of knot applied is important to secure the members in place so that the junction does not slip and fail. Coconut fiber ropes, hemp fiber ropes, jute ropes or even old clothes are used for tying. However, ropes when exposed to the weather may decay and fail, hence would require to be replaced from time to time.

Use of bolts and nuts

Using bolts and nuts involve drilling holes in the members to be joined. However, drilling holes in bamboo is different from that in timber. In bamboo holes are drilled through constituent members in the internodal regions, and not in the nodes. It may be noted here that nodes in bamboo are very strong zones, unlike in wood, hence even trying to drill holes through them would be impractical.

Once the members are ready with properly drilled holes; bolts are driven through them and secured with nuts to achieve a junction. Overlapping of the constituent bamboo members is mandatory for such junctions (Fig. 6).

Fig. 6 Joining bamboo by means of bolts and nuts. Reproduced from Smithsonian Cooper-Hewitt, National Design Museum, 2010. Millennium school bamboo project. Available at: <https://www.designother90.org/solution/millennium-school-bamboo-project/>.

Fig. 7 Bamboo junction by Renzo Piano using plates. Reproduced from Georg-Christof, V.B., 2009. Bambú brasileiro or the future of a material. Stylepark. Available at: <https://www.stylepark.com/en/news/bambu-brasileiro-or-the-future-of-a-material>.

Fig. 8 Joining of bamboo using industrial glue. Reproduced from Wisdom, T., 2012. Natural fiber rope and epoxy joints. Available at: <https://www.flickr.com/photos/thomwisdom/7358920860>.

Use of plates

In the above mentioned two bamboo jointing methods, involving use of ropes and bolts and nuts, bamboo members forming a junction needs to be overlapped. However, there are situations when one needs to avoid the overlapping. Forming bamboo junctions using plates is a jointing method that allow one to achieve junctions avoiding overlap. Plates are also used in bamboo junctions to achieve longer lengths in bamboo where two members are joined tip to tip. Such junctions are also used to accommodate two bamboo members meeting at an angle in the same plane. Again, plates can be used to form complex junctions where the design of the plate is modified to act like florets to achieve joining of more than two members lying on various planes (Fig. 7).

Use of carpentry joints

Standard carpentry joints which involve cutting a groove, interlocking two members etc. can be used in bamboo with intuitive modifications. Lap joint, dovetail joint, and mortise and tenon joints are examples of some of the widely used carpentry joints, used in design of bamboo junctions.

Use of glue

Industrial adhesives are mostly used in combination with bolts or rope made junctions for further securing the joint. PVC glues are also used which form a protective membrane or layer over the junction and protect the underlying material from wear and tear, thus extending its life. Designing bicycles (Fig. 8) and furniture using industrial glue are two of the extensive uses of glue in industrial design.

Apart from securing bamboo junctions, as mentioned above, industrial glues are also extensively used in making bamboo boards, bamboo doors-windows and utensils made from bamboo dust.

Conclusion

The search for sustainable building material has brought bamboo from the fold of age old artisanal use to the arena of engineered investigation. Observing its similarity with timber, the artisans has initially adapted timber fastening and jointing methods to develop bamboo junctions. Use of ropes and carpentry joints in low-tech bamboo junctions represent this stage of development, which has its own area of requirement and is still continuing. However, rise in its engineered application has resulted in the development of the hi-tech bamboo junctions using bolts and nuts, plates and industrial glue.

Apart from the above often-used ones, architects and designers have often created special bamboo junctions addressing specific design needs. These are custom solutions and are mostly not generic in nature. Further, some of these junctions may find wider use in future. However, a generic lack of documentation, variation in bamboo from region to region, lack of strength data and other factors hinders their application. Bamboo is still undergoing a lot of research and there are newer junctions which are yet to be tested for stability, ease of fabrication and longevity. These research heavily bring into use modern industrial design principles of modularity, fabrication standardization and mix material usage.

Sustainability and Green Building Rating Systems: A Critical Analysis to Advance Sustainable Performance

Laura Florez, University College London, London, United Kingdom

Green Building Rating Systems

Green buildings are structures that aim to minimize the environmental, economic, and social impacts of construction and optimize the use of resources. Green buildings use more environmentally friendly materials and ensure efficient use of natural resources such as water and energy with minimal generation of waste. Technologies and innovative systems such as efficient cooling, lighting, and energy operators that automatically adjust room temperature, control internal lighting, reuse water, and consume less energy are also implemented in green buildings. Additionally, green buildings improve indoor environmental quality and thermal comfort reducing the sick building syndrome and increasing the well-being of its occupants and their quality of life.

Green building rating systems are methods used to certify green buildings and serve as a means of reducing construction impacts along the entire life cycle. Rating systems measure performance of building assets across a range of sustainability principles. These require an integrated design process to build projects that are environmentally responsible and resource-efficient from concept to design, construction, operation, maintenance, renovation, and demolition. A primary reason for the creation of rating systems was the need to more clearly define, implement, and measure green goals. Some rating systems are single-attribute, focusing exclusively on water or energy, while others are multi-attribute addressing not only water and energy but emissions, toxicity, and overall environmental, economic and social performance. Even though the philosophy, approach, and certification method vary among rating systems, a shared objective is that certified projects are designed to reduce the overall impact of the built environment, the natural environment, and enhance human health and well-being.

There are multiple factors that should be considered to determine which rating system should be used to certify a building. Firstly, identify what organization is making the assessment and is it being done by a first, second or third party. A first-party assessment is one that comes directly from an organization that is associated with the entity applying for certification or who may benefit from it. An interested party such as a trade association performs a second-party assessment. A third-party assessment is conducted by an independent party that has no financial interest or ties to the outcome of the assessment. Secondly, the type of certification system pursued for a project depends upon that singular project since none of these certification systems are one-size-fits all. Some rating systems address project types such as single-family houses and commercial buildings while others address entire neighbourhoods and communities. There are rating systems available for new construction and major renovations, which focus on decisions made in the planning and design process and actions taken through construction. Other systems are developed for existing buildings, which focus on operations and maintenance throughout the life of the building. The dynamic nature of projects might prohibit one system but favour another. Ultimately, the choice is dependent upon the uniqueness of each project and the project needs and requirements such as the location, size, budget, and overall goals. By comparing essential requirements such as cost, ease of use, and building performance, decisions can be made regarding, which building rating system is applicable and what level of certification is possible.

Pursuing a Green Building Certification

There are various reasons for pursuing a green building certification for a project. Certification provides verification of the accomplishment of green goals, and can be a valuable marketing tool for owners, and design and construction teams through the process of developing a sustainable building. Certification can also be a way to provide an incentive for clients, owners and users to promote highly sustainable construction practices and minimize the environmental and social impacts of construction projects. Rating systems also outline what green standards need to be followed and what type of products should be included in construction specifications. Economic and environmental benefits to sustainable design, often achieved through green building rating certification, have also been quantified and have served to promote new projects. Multiple studies have found that energy, carbon, water, and waste can be reduced, resulting in savings of 40%–60% in costs. Operating costs of green buildings can also be reduced by 8%–13% while increasing its value up to 7.5% compared to regular buildings. Many sustainable buildings have also seen increases of up to 10% on return on investment, 6% in occupancy, and 3% in rent. Other benefits of green buildings such as higher productivity and increased occupant health have been attributed to better indoor environmental quality, increase in natural daylighting, and healthier materials and products. While these benefits are possible, it is important to note that they are dependent upon factors such as climate, topography, timing, credit synergies, and local building standards (GhaffarianHoseini *et al.*, 2013). Additionally, it is worth noting that a building can be sustainable and can be built according to green specifications, but not necessarily needs to be certified to achieve or comply sustainable goals. Certification in most cases is a voluntary process, but recently it has become a standard for construction projects and a requirement for some private and government-owned buildings.

Performance Evaluation in Rating Systems

Two kinds of approaches have been followed to develop performance metrics for rating systems. The first is based on a multi-criteria credit system in which several credits in prescribed categories evaluate the level of sustainability and the project is awarded points. This system follows a prescriptive path by evaluating whether the project implements features or not. The second approach is based on indicators quantified by means of a life-cycle assessment (LCA) procedure. The LCA analysis is a scientific method and is more complex. This system follows a performance path by looking at the functioning and operation of the project. Building sustainability can be assessed using several methods and labelling tools, which are characterized by different credits, weights, calculation procedures, and performance analyses. These differences can impact the final scores and the level of sustainability achieved by each project. Furthermore, rating methods are defined according to local climate and geographical conditions resulting in the adaptation of sustainability to a local or national level. Even the ranking of criteria is also adapted to local conditions and may not be similar at the international level. However, at the global level, building sustainability should be comparable among different conditions and countries despite the differences in features and methods and that poses a challenge.

Building rating systems are in a state of change and evolution and continue to be refined to reflect new standards and goals for achieving ever-higher levels of sustainability at the global level. Therefore, it is essential to investigate the most current versions of these systems to gain an understanding of requirements that must be met in order to achieve the best results. There are approximately 600 rating systems around the world (Vierira, 2011). Very comprehensive inventories of rating systems and tools for green assessment and certification can be found in the Whole Building Design Guide (WBDG), the Global Reporting Initiative (GRI), and the World Green Building Council (WGBC), which is an organization that gathers the national green building councils around the world. The BREEAM was the first rating system developed in the early 1990s and numerous other methodologies have followed it.

This review focuses on the United Kingdom's BREEAM, the United States' LEED, the Arab States' GSAS and India's GRIHA. The rationale for selecting these rating systems is based on comparing two well-established rating systems that were developed to be adaptable to different regions (BREEAM and LEED) to two rating systems that are region-specific, are in their earlier stages, and have seen an increase in their use (GSAS and GRIHA). Future directions and alternatives are also discussed that advance rating systems and sustainable performance measurement alternatives.

BREEAM

The BREEAM was developed in 1990 in the U.K. and it was the first green building rating system in the world. Operated by the Building Research Establishment (BRE), it is widely used throughout the UK the EU, EFTA member states, and EU candidates. Due to its longevity, its use is widespread, and its certification has highly been recognized as influential to almost all later green building rating systems developed such as LEED. BREEAM evaluates a building's lifecycle in view to design, built, operation, and refurbishment and it is widely used because of its flexibility. It assesses not only local codes and conditions, but also allows application in international buildings. As of 2018, BREEAM has issued over 560,000 certifications in over 80 countries and it is expected that both the number of projects certified as well as the countries adapting it will follow an incremental pattern. BREEAM is a multi-attribute rating and certification system that follows a multi-tiered process with pre-assessment and third-party consultant guidance. It is used for the assessment of new construction, communities, in-use buildings, and eco-homes and widely used by planners, local authorities, developers and investors. The assessment process uses recognized measures of performance to compare them against a set of established benchmarks in the areas of energy and water use, internal environment (health and well-being), pollution, transport, materials, waste, ecology, and management processes. Even though all the sustainability criteria are assessed by BREEAM, the environmental factor is still predominant with eight main categories.

LEED

The United States Green Building Council (USGBC) created the LEED in 1998. LEED has been accepted as the most widespread and recognized rating system in the United States, after having established strong credibility among the experts. It is widely used by architects, engineers, and designers that want to earn LEED certification. Since its creation as a voluntary standard measure, the LEED system has become an appropriate tool for the assessment of green buildings, becoming a reference system for the design, construction, and operation of green buildings beyond the United States. The WGBC states that adaptations of the LEED system have been developed or are in the process of implementation in Central and South America, Asia, Middle East, and India among others. As of 2018, LEED has issued over 78,000 certifications in more than 150 countries and it is considered the world's most widely adopted rating system based on the number of countries that have adapted it. LEED is a multi-attribute rating and certification system, which assesses different building types such as new construction, existing buildings, commercial interiors, core and shell, schools, retail, healthcare, homes, and neighbourhood development. LEED has mandatory prerequisites such as minimum energy and water-use reduction, recycling collection, and tobacco smoke control. If the prerequisites are achieved, then a project can earn points in seven categories: site selection, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, regional priority, and innovation in design. Within each category there are credits that pertain to specific strategies for sustainability, such as the use of low-emitting products, reduced water consumption, energy efficiency, access

to public transportation, recycled content, renewable energy, and daylighting. It uses a prescriptive and feature-oriented approach rather than a performance approach. There are no on-site visits required and certification can occur upon completion of a project. Even though all the sustainability criteria are assessed by LEED, the environmental factors are predominant within the seven categories. Additionally, some economic factors are also considered and play a key role within the categories.

GSAS

The Global Sustainability Assessment System (GSAS) is the first performance-based system in the Middle East and North Africa (MENA) region and Qatar, developed for rating green buildings and infrastructure. GSAS was established by the Gulf Organization for Research and Development (GORD) through collaboration with the University of Pennsylvania and Georgia Tech for the development of a sustainable built environment that minimizes the ecological impact while addressing specific environmental, social, and cultural needs of the region. GSAS was developed in 2007 by drawing best practices adopted from a comprehensive review of more than 40 regional and international building rating systems, tools, and guidelines. The review was later narrowed to six well-known rating systems including BREEAM and LEED, in which MENA's specific needs and regional requirements were integrated with sustainability goals. By combining the best features from the most well-established rating systems with new facets and dimensions, GSAS offers a more comprehensive approach to sustainability requirements and goals from a macro level to a micro level. It uses a quantifiable and result-oriented approach rather than a prescriptive and feature-oriented approach. As of 2018, GSAS has issued over 200 certifications in the MENA region.

GSAS is a multi-attribute rating and certification system, which assesses different building types such as districts and infrastructure, commercial, mosques, neighbourhoods, parks, residential, schools, hotels, light industry and healthcare among others. Through the life cycle approach, GSAS evaluates performance in eight categories: urban connectivity, site, energy, water, materials, indoor/outdoor environment, cultural and economic value, and management and operations. Even though all the sustainability criteria are assessed by GSAS, the environmental factors are predominant with four categories. Additionally, a considerable number of points are awarded to management and operations.

GRIHA

The Green Rating for Integrated Habitat Assessment (GRIHA) is the rating system for green buildings and infrastructure developed in India in 2007. The GRIHA was established by the government and the Ministry of New and Renewable Energy (MNRE) and the Energy and Resources Institute (TERI) to assess the performance of buildings against nationally acceptable benchmarks. It evaluates the environmental performance of a building holistically over its entire life cycle, providing a standard for green buildings. The GRIHA, based on accepted energy and environmental principles, balances established practices and emerging concepts at both national and international levels. It has been developed to design and evaluate new buildings and buildings that are still at the inception stages with a minimum area of 2500 m². The latest version published in 2015 assesses performance or predicted performance over the life cycle from pre-construction to planning, construction, operation, and maintenance. As of 2018, GRIHA has issued over 500 certifications in India and it is expected that the number of projects certified will follow an incremental pattern.

GRIHA is a performance-oriented system, where points are earned for meeting the design and performance intent of the criteria. There are six criteria: site planning, energy and occupant comfort, water savings, waste management, sustainable building material, and social aspects. Each criterion has certain points assigned to it and a project demonstrating compliance with a criterion would receive the associated points. There are 100 points available within these categories with mandatory and optional criteria. Mandatory prerequisites include water quality, tobacco smoke control, and zero ozone-depletion-potential materials. Within each category there are criteria that pertain to specific strategies for sustainability such as low impact design, water reutilization, reduced embodied energy, labor safety and sanitation, air and water pollution control, reduction in waste during construction, and operation and maintenance. GRIHA assesses different building types such as affordable housing, offices, retail spaces, institutional buildings, hotels, hospitals, healthcare facilities, residential, and multi-family high rise buildings among others. Even though all the sustainability criteria are assessed by GRIHA, the environmental factors are predominant. In the next section, the four rating systems are analysed and compared in detail.

Features of BREEAM, LEED, GSAS, and GRIHA

Table 1 shows the main features of the four rating systems including coverage, first and latest version, rating method, rating level, and main categories. BREEAM served as a basis for the development of the later rating systems, while LEED continues to be the most-used rating system around the world. As shown in **Table 1**, all four rating systems released their latest versions recently, which shows that the organisations responsible for their management and release are making efforts to revise and update its criteria to follow with the newest developments in green buildings.

Table 1 Main features of rating systems

Rating system	Coverage	First and last version	Rating method	Rating level	Categories	
BREEAM	80 countries	1990 2016	Pre-weighted categories	Pass ≥ 30 Good ≥ 45 Very good ≥ 55 Excellent ≥ 70 Outstanding ≥ 85	Management Health & wellbeing Energy Transport Water	Material Waste Land use & ecology Pollution Innovation
LEED	150 countries	1998 2013	Credits and points	Certified ≥ 40 Silver ≥ 50 Gold ≥ 60 Platinum ≥ 80	Integrative process Indoor environment quality Energy & atmosphere Location & transportation	Water efficiency Material & resources Sustainable sites Regional priority
GSAS	MENA region	2007 2017	Score and criteria with weights	1 star $0.00 < x \leq 0.50$ 2 stars $0.50 < x \leq 1.00$ 3 stars $1.00 < x \leq 1.50$ 4 stars $1.50 < x \leq 2.00$ 5 stars $2.00 < x \leq 2.50$ 6 stars $2.50 < x \leq 3.00$	Urban connectivity Site Energy Water	Innovation Materials Indoor/outdoor environment Cultural & economic value Management & operations
GRIHA	India	2007 2015	Score and criteria with weights	1 star 50–60 2 stars 61–70 3 stars 71–80 4 stars 81–90 5 stars 91–100	Site planning Construction management Occupant comfort and wellbeing Sustainable building materials Performance monitoring and validation Innovation	

BREEAM and LEED were developed only by non-profit third-party organisations. In addition to third party organisations, GSAS was established with significant input from best practices of previous rating systems and collaboration from academia and industry.

GRIHA was also developed by third-party organisations and with a dominant role from the government and the ministry of energy. It is worth noting that the four rating systems are voluntary tools. However, certification has become a mandatory requirement in some regions or for specific purposes. BREEAM is a mandatory requirement to achieve funding from the Department of Health and Education in the UK. California is the first state in the US that requires high-rise residential projects to be certified LEED silver since 2010. GRIHA rating is mandatory for government buildings as a precondition for departments to get subsidies and other financial assistance for green development since 2011. The GSAS rating is becoming mandatory for new developments funded by the government. The following comparison is focused on new construction manuals, as all the rating systems have a certification for this type of project. For GRIHA, the affordable housing guidelines were used for the comparison.

Coverage

BREEAM and LEED have a significant number of green certified buildings globally. Although both rating systems consider regional characteristics, climate, and culture, other countries besides the UK and the US have adopted (and could adopt) BREEAM and LEED. The flexibility and applicability of GSAS and GRIHA is still limited because they were established only about a decade ago. They were developed to be more region-specific and towards certifying domestic projects leading to fewer number of certifications.

Rating Method

The rating method differs among the green building rating systems. BREEAM has 134 available points (excluding the non-residential building items). It is a multi-attribute certification system that follows a multi-tiered process with pre-assessment and third-party consultant guidance. During the assessment process, the project's metrics of performance are compared against a set of established benchmarks. If the performance is achieved, a score is given. The final scoring level is determined by considering the

score achieved and the pre-weight factor given to each category. BREEAM scoring is based on performance and weights so it is more complex. Additionally, it is stricter in its criteria for achieving credits as it sets absolute parameters.

LEED has 100 available points and it is based on prerequisites and credits. The prerequisites are mandatory; thus, all projects must meet these in order to achieve certification. To earn certification, LEED follows a prescriptive approach in which the project is evaluated to determine whether it has specific features or not. If the project has the features prescribed in the credits, the points are achieved. All the points are added to calculate the final score and certification level. Only a few credits evaluate performance. LEED is considered a transparent approach for calculating points as the evaluation determines whether the project has a feature or not, without requiring a quantifiable measure. Additionally, it is simpler in its criteria for achieving credits as it sets relative percentage improvements or reduction targets.

GSAS is a system with a maximum scoring level of 3.00 and uses key performance indicators to score the project and assess the criteria on each category. The categories have a designated pre-weighted rank based on the analytical hierarchy process (AHP). There is a maximum value the project can achieve, within each category, and based on its compliance and the weight assigned, the project is awarded a score for each criterion. The sum of the scores determine the certification level. GSAS is a performance-based approach in which results are quantified and has designated an importance factor for each category. Like BREEAM, the scoring is more complex as it is based on weights.

GRIHA has 100 points available and it combines a prescriptive and performance path. While the intent of some of the criteria is based on compliance, there are others which need to be validated on-site through performance monitoring. The points evaluated through performance are awarded provisionally while certification is in process and are converted into firm points after monitoring, validation, and evidence. Points achieved in each category are added to determine the certification score. GRIHA combines the transparent approach of compliance and the stricter approach requiring quantifiable measures.

Certification Process

BREEAM certification process starts with the project's registration with the BRE and appointment of an assessor to assess the project. A pre-assessment process is carried out with the assessor and the project's documentation and information are prepared. The assessor reviews the documentation and determines the compliance with the standard. Later the documentation is sent to the BRE to establish the certification level. Certification is awarded for the entire life of the building.

LEED follows an online certification process. Project teams are required to compile documentation to show compliance with its requirements and upload this documentation to the LEED Online website. The Green Building Certification Institute (GBCI) then reviews the documentation and a certification is earned if all prerequisites and enough credits are earned. There are no on-site visits required and certification can occur upon completion of construction and as-built documentation showing compliance. Certification is awarded for the entire life of the building.

GSAS certification process is handled through the online certification management portal and all projects aiming to obtain the certification must register on the GSAS gate. The gate portal is the main database where all the required documents and evidence are prepared and submitted. The review follows a two-step process: a desk review to ensure submission of the requirements and an on-site audit to verify compliance. Additionally, there is a 12-month assessment period in which building operations are monitored to evaluate the sustainability of the project. Even though a building can still obtain the certification based on the as-built specifications without submission of data, the scores will be based on submissions and the data (if provided) can lower the overall rating achieved. Certification is awarded for four years upon which re-certification can be applied.

GRIHA compliance, as specified in the relevant criterion, must be submitted in the prescribed format. The certification follows the GRIHA online process. Project teams are required to register the project before conception and to show compliance with its requirements by uploading this documentation to the website. The documentation shall be sent for a third-party review and three on-site visits are required during the project execution for auditing the green features and on-site performance monitoring. The GRIHA council then reviews the documentation and gives provisional points with an option to resubmit the documentation if there is a desire to increase the certification. The certification is awarded for five years and there is an audit after the first year of commissioning the building. GRIHA reserves the right to conduct random visits and audit any credit that has been awarded.

It is worth noting that BREEAM, LEED, and GSAS can be used to certify new construction and existing buildings and infrastructure while GRIHA can only be used to certify new construction, as projects must apply for certification as early as the design stage.

Life-Cycle Phases and Evaluation Approach

The project's life-cycle phases considered in each rating system vary. GSAS considers design, construction, and operation while BREEAM and LEED consider design, construction, operation, and refurbishment. GRIHA has a more holistic approach that considers pre-construction, pre-design, design, construction, operations, and maintenance.

Regarding the evaluation approach, whether is prescriptive-based or performance-based, there are some differences as well. BREEAM follows a combination of prescriptive and performance based evaluation. LEED follows a prescriptive approach in which the compliance of a project is evaluated one time, that is, if a project has a determined feature then points are awarded towards

Fig. 1 Distribution of key categories.

certification. GRIHA is a prescriptive and performance-based system. Some criteria are evaluated through compliance, whereas others need to be validated on-site through verification, monitoring and validation. The LCA is considered only by BREEAM and GSAS.

Categories

Regarding the number of categories, BREEAM has the maximum number (10), which is slightly higher than the nine of LEED, eight of GSAS, and six from GRIHA. BREEAM, LEED, and GSAS share a similar pattern in the characteristics of the categories. GSAS has a strong influence and is based on BREEAM and LEED (among other rating systems) hence its similarities. Although GRIHA has an indirect influence from BREEAM, it was established through the cooperation of third-party organisations, the government and the ministry of energy leading to the difference and a reduced number of categories.

Key Categories

Multiple studies have used key categories to compare rating systems. In this article, eight categories are used in the comparison: site, energy, water, indoor environmental quality (IEQ), material, waste and pollution, management, and other. **Fig. 1** shows a radar diagram for the distribution of key categories for each rating system. Energy is still the most prevalent category among the rating systems: LEED has the maximum credits related to it (30%), while GRIHA has the least credits (18%). It is worth noting that all rating systems have a specific energy category: BREEAM has “Energy”, LEED has “Energy and Atmosphere”, GSAS has “Energy performance”, and GRIHA has “Energy and occupant comfort”.

Water is the second most important as all the rating systems have a water-designated category: BREEAM and GSAS have “Water”, while LEED has “Water efficiency”. GRIHA has “Water savings” and it is the rating system that gives more importance to water, as it accounts for 18% of its credits. All the four rating systems follow similar water-saving indicators such as reduction in water consumption, innovative water technology, and water-efficient systems and technologies. GRIHA has an additional consideration aiming to reduce water consumption during construction.

The third most prevalent category is site. All the rating systems have a similar distribution of criteria related to this category: LEED (14.78%), BREEAM (10.77%), GSAS (13.00%), and GRIHA (14.71%). All the rating systems consider similar site characteristics related to the preservation and conservation of species and local environmental features, site amenities, and the influence of the design. BREEAM has an additional consideration aiming to reduce natural and risk hazards.

BREEAM, LEED and GSAS have a similar distribution for IEQ-related criteria (between 12% and 15%) while GRIHA has only 2.94%. The main reason for the IEQ consideration is the increasing concern about the sick building syndrome, tobacco smoke control, and toxic air pollutants. BREEAM is by far the rating system that considers more criteria related to management (17.89%)

by encouraging projects to integrate practices in the design stage and focus on performance targets early to influence decision making and reduce unnecessary costs. GSAS has not criteria directly related to waste and pollution.

The materials category has the same pattern of credit/point allocation among the rating systems: LEED (10.43%), BREEAM (10%), GSAS (10%), and GRIHA (8.82%). LEED materials criteria focuses on improving the recycling rate of building materials and use of local materials, while BREEAM main concerns are on adopting a method of purchasing as to save materials consumption by controlling the material procurement channels. GRIHA material criteria focus on using materials with low emissions and materials for energy efficiency. GSAS main concern is on increasing the use of regional and recycled materials, and materials reuse and design for disassembly.

Three Pillars of Sustainability

Another interesting comparison is to look at the three pillars of sustainability and determine the distribution among the rating systems. Environment is the main factor for all rating systems. More than 60% of the subcategories are related to environmental aspects. Two different environmental effects have been considered across the rating systems. One effect is related to the influence of the site characteristics on the building, which is typically accounted for with site-related criteria. Site considers aspects related to the preservation and conservation of species and local environmental features, natural hazards and risks associated to the site characteristics, site amenities and the influence of the design on the building. All the rating systems consider the mentioned environmental effects except for natural hazards and risks that are only accounted for in BREEAM. The second effect is related to the building impacts on the outdoor environment, both during construction and operational phases, which is typically accounted for in outdoor quality criteria. BREEAM has a management criterion mainly focused on indoor quality. GSAS has a category for indoor and outdoor environment and GRIHA for construction management. Although the number of categories addressing social factors has increased with a focus in culture, comfort, health, and well-being, this aspect is still modest. GSAS has some criterion related to minimum level of safety facilities for construction workers.

BREEAM is the only rating system that addresses economic factors. In addition to the environmental, economic, and social aspects, some rating systems share similar categories to address operations and account for exemplary performance. For instance, BREEAM and GSAS have a category that addresses operations and management while GRIHA goes further and has a category that evaluates performance monitoring. LEED is the only rating system that does not have a category related to operations and management, although indirectly assesses some aspects through the integrative process category. BREEAM, LEED, and GRIHA have an innovation category that promotes new developments and strategies to achieving sustainability that go beyond the minimal standards. GSAS has an education category that aims to raise awareness of energy uses by its occupants by pointing out behavioural changes that minimize the resource consumption. BREEAM, GSAS and GRIHA have criteria that considers visual comfort and adequate noise. LEED is the only rating system that does not assess visual and acoustic aspects.

Meeting Targets

Since all of these rating systems are operational for a substantial time, it is relevant to determine whether these rating systems are meeting the quantifiable targets for which they were developed. BREEAM sets absolute parameters for achieving credits, which sets stricter measures for compliance. For instance, it specifies exact targets for energy performance ratios such as 0.06 for achieving one credit and 0.09 for 15 credits. As it is a one time metric, the evaluation does not consider improvements or benchmarking values. On the contrary, LEED establishes relative percentage improvement or reduction targets, thus it is easier for projects to meet the targets for achieving points. For instance, a table is provided in which the energy simulation results of the building are evaluated against benchmarks for existing buildings. Thus if the simulation shows that there is a 42% improvement then 16 points could be awarded (Doan *et al.*, 2017). With these standards, note that BREEAM helps to achieve certified projects while LEED helps to develop green buildings at the global level.

GRIHA uses a similar approach to LEED. It establishes relative percentage improvement or reduction targets, thus it is easier for projects to meet the targets for achieving points. For instance, a table is provided in which the energy consumption of the building is compared against the GRIHA benchmark. Thus if there is a reduction of 10% compared to the base case then 2 points are awarded and for a reduction of 50% a maximum of 10 points are awarded. One challenge to achieving points is that consumption depends on the number of occupants on the building and the benchmark does not differentiate between a high or low occupancy building hence, it has a direct impact on buildings with many occupants.

GSAS has a mixed approach in which some credits are performance-based and some are prescriptive. In addition, it has a weighting system for credits similar to BREEAM. For instance, an energy compliance requirement states that air-conditioning equipment should have a minimum EER of 10 or better equivalent in the market and light fixtures should be LED, CFL, T5 or similar efficient in the market. Note that the use of products depends on what is available in the market, thus if some products become unavailable then it makes it impossible for designers to achieve these points or becomes increasingly challenging to demonstrate compliance. The performance-based credits evaluate the energy consumption of the building. For instance, a building's energy consumption after the simulation is compared to the benchmark of other buildings. However, this approach does not consider that both buildings are functionally equivalent. The comparison should be on the basis of normative assumptions of their usage and internal processes so designers have a challenge in establishing a fair comparison.

Discussion

This article provided a critical review on four rating systems for green buildings and explored its considerations, similarities, advantages, and challenges. The review included the BREEAM, LEED, GSAS, and GRIHA. The review confirms that BREEAM and LEED continue to be the most established and well-known rating systems across the world, not only by the number of projects certified, but also in terms of the number of countries that have adapted and use them as a reference for certification of green buildings. BREEAM and LEED also provide a great marketing value for buildings and their strict and straightforward approach has contributed to their increased use. BREEAM is the first rating system developed which has established its credibility among the experts and continues to be the most used rating system across the world with about 550,000 project certifications. BREEAM is stricter in its criteria for achieving credits as it sets absolute parameters. LEED has a transparent system that uses a relative percentage improvement or reduction targets. It is easy to use and adapt to specific conditions given its flexible scheme. With over 150 countries, LEED is the most-widely used rating system based on the number of countries. GSAS is a new rating system for the MENA region, and has adapted the transparency of LEED and strictness of BREEAM. It includes criteria related to performance, operations, quantification of results. GRIHA is also a new rating system that operates only in India with a focus on new construction that includes performance and operations.

Because of their adaptability to different conditions, BREEAM and LEED use international standards, so it is argued that they are not designed for specific local conditions. For instance, LEED has energy considerations primarily based on per capita energy consumption in developed nations like the US, which does not reflect per capita energy conditions in developing countries, which have a low consumption compared to developed nations. Additionally, the international codes implemented in BREEAM and LEED usually take a hypothetical case while rating systems adaptable to local conditions work with an absolute number, which is easily understood. LEED promotes the use of certain products like glass and air-conditioning equipment while BREEAM promotes the use of energy solar panels. GRIHA and GSAS have the advantage to be very comprehensive and adaptable to specific conditions, which makes it more suitable for local projects and realities. However, the newest rating systems do not have a higher exposure from other parts of the world, so LEED and BREEAM continue to be more acceptable because of their rigour and trajectory to multinationals and owners who are prime investors and are looking for developing globally recognized projects.

Although BREEAM, LEED, GRIHA and GSAS have environmental and social aspects, the economic aspect is still under-represented. BREEAM has a sub category related to economic (management) aspects, but no considerations on the costs. Economic and financial aspects are determinant for the success of a building. Research in sustainable buildings has stated that costs and the scarce budget are common reasons for the bankruptcy of many green buildings so there is a pressing need for a more holistic approach that accounts for the economic aspects of the building, evaluates life-cycle cost performance and minimizes costs (Pagliaro *et al.*, 2015). Land costs, occupancy costs, construction costs, demolition costs, and professional fees are some of the economic considerations that should be included in rating systems. Furthermore, it is necessary to pay attention to the relationship between environmental performance and economic performance and the interrelationship between these two aspects. A sustainable building should account for economic performance and costs.

Another aspect that has a minimal consideration is the sustainability performance of the construction phase. During the construction phase in which the project is built, numerous stakeholders and participants are directly involved, and this can have a direct impact on their needs and well-being. GRIHA has three criteria related to providing sanitation and safety facilities for construction workers, efficient water use, and air pollution reduction during construction. However, none of the rating systems has considered a broader approach of sustainability of construction operations. For instance, social sustainability is an opportunity to achieve better standards of living by promoting practices and responsible ways to manage people by considering people's needs and expectations (Alwaer and Clements-Croome, 2010). Employment and training opportunities for workers can be assessed to determine whether the project is increasing the well-being of workers and providing job continuity. The economic impact of construction can also be assessed by quantifying the financial costs of the project while minimizing the costs (reducing errors and omissions). The environmental factor could be addressed by reducing the embodied energy of the project and the pollution and emissions of equipment and machinery.

Although site conditions are considered in the rating systems, culture is another criterion that has not been included in the rating systems. This is a key aspect in relation to local conditions of the project, the preservation of intangible attributes and specific conditions that enhance inhabitant's quality of life. Credit criteria focusing on social sustainability such as education and awareness have only been considered in GSAS. Other aspects that have not been included and that are key to achieve a complete level of sustainability are employment, stakeholder inclusion, and resilience for adaptation and mitigation (Fernandez-Sanchez and Rodriguez-Lopez, 2010; Chandratilake and Dias, 2015).

The review confirms that no rating scheme from the four that were evaluated can assess a building project in all aspects of sustainability. Therefore, a question that must be raised is the following: Are rating systems effective tools to realize substantial reductions on the impacts of buildings and infrastructure? Some researchers agree that there is no definition of what constitutes sustainable performance (Lee, 2013). The list may include for instance energy efficiency, water reduction, low contaminants, people's well-being and many others. How many criteria should be included in the list for it to be comprehensive? The acceptance of a definition of sustainable performance is critical to creating a common language and facilitating communication to establish rating tools that measure performance. Consequently, developing indicators becomes critical as these serve to evaluate and measure performance. Indicators highlight trends and are used to quantify sustainability across a range of sustainable principles (Singh *et al.*, 2009). As buildings become systems (and in some cases part of a larger system), rating tools may consider integrating

indicators into models to evaluate trade-offs and the interrelationships and overlapping dimensions of sustainability criteria and building components (Florez, 2012). If rating systems integrate indicators into models to measure performance, a more holistic and realistic approach can be implemented to advance sustainable performance metrics. A model in which, sets of building components become building systems and building systems become part of larger systems, allows comprehensively measuring and assessing sustainable performance. This can be a novel approach to the way rating systems become effective tools to reduce impacts of buildings and infrastructure.

Conclusions

A critical review of four rating systems for green buildings was conducted including BREEAM, LEED, GRIHA and GSAS. It was found that the environmental factors are still predominant in the evaluation of green buildings. Energy is the main category while water is the less evaluated criteria followed by materials. The consideration of social aspects is increasing, although are still marginally considered. Economic aspects and financial considerations are mostly neglected in all the rating systems. The reader is referred to Illankoon *et al.* (2017), Zuo and Zao (2014), Berardi (2013), and Mattoni *et al.* (2018) for critical reviews on other rating systems.

Well-established rating systems (BREEAM and LEED) and new rating systems (GSAS and GRIHA) have some differences regarding the inclusion of a more comprehensive life-cycle perspective and the evaluation of performance and operations. While BREEAM and LEED evaluate a building based on the documentation provided and as-built evidence to determine the certification level, GSAS and GRIHA evaluate a project based on documentation, as-built evidence, and on-site audits to verify that real-time operations match the evidence. A certification level is then awarded to the project. Note that GRIHA also allows a project to revise the documentation and re-apply for certification if a higher level of certification is desired. BREEAM and LEED award a one-time certification while GSAS and GRIHA award a limited-time certification after which the building must be reassessed to maintain its certificate.

This analysis also shows that there are still sustainability issues that are only included in a few rating systems but should be considered in all ratings in order to provide a certification that includes all aspects of sustainability. For instance, environmental hazards and risks, LCA aspects, global warming, noise and light pollution in outdoor environment should be included. There are also limitations in the way the criteria are formulated and evaluated. All the rating systems focus on building features or the final building and infrastructure project and its performance, with little attention being paid to the performance and the impact of the building during the construction phase.

Rating systems need to perform an assessment of its principles: (1) science-based-decision and results must be reproduced by others using the same standard; (2) transparent-standards and process for awarding the certification should be transparent and open for examination; (3) objective-certification body should not have any conflict; (4) progressive-standards should advance industry practices not simply reward business as usual.

Global sustainability and local sustainability are also concepts that need to be considered when evaluating rating systems (Illankoon *et al.*, 2017). Although global sustainability should lead to include in every rating system the same fundamental credits, the non-homogeneous assignment of weights is a natural consequence of local sustainability. BREEAM and LEED were developed to be global standards for green buildings and provide a broader consideration of sustainability aspects, while GSAS and GRIHA have included specific rankings in the criteria aiming to focus on local considerations and conditions. This review is a practical reference of building rating systems and could be valuable for both green practitioners and researchers to have an overall understanding of BREEAM, LEED, GRIHA and GSAS. Differences, advantages and strengths were identified.

The growing need to deal with economic, environmental, and social impacts in construction poses a challenge to develop rating systems that help implement sustainable practices. Sustainability is realized when a building and infrastructure project meets economic, environmental, and social factors. Green building rating systems have been developed across the world to implement sustainability principles and promote the use of features and systems that reduce construction impacts. This article is a practical reference of building rating systems and establishes the extent to which these methods assess green buildings in all aspects of sustainability. The analysis conducted gives practitioners in the built environment and construction industry a deeper knowledge and understanding of the aspects included in BREEAM, LEED, GRIHA, and GSAS. Although the rating systems reviewed in this article have incorporated key criteria to measure sustainability, no rating scheme can assess a project in all aspects of sustainability. The acceptance of a definition of sustainability is critical to creating a common language and facilitating communication, while minimizing the impacts of buildings and infrastructure. Additionally, there is a need to integrate indicators from rating systems into models to provide more useful guidance for efforts to a transition towards sustainability (Singh *et al.*, 2009). By integrating indicators into models, the interrelationships and the overlapping dimensions of the criteria could be covered (Florez, 2012). Models can be used to identify the way in which tasks are unsustainable, assist decision makers to determine which actions should or should not be taken (Singh *et al.*, 2009), give effective feedback (Alwaer and Clements-Croome, 2010) and provide useful evidence to support project administration (Fernandez-Sanchez and Rodriguez-Lopez, 2010).

The analysis performed in this review gives green building users and researchers a deeper knowledge of the aspects included in rating systems, methods of calculation and awards. It also lays the groundwork for identifying common issues that should be included in rating systems for a comprehensive analysis of green goals throughout the life cycle of buildings and infrastructure. This review of the four selected rating schemes may not reflect the overall trend of rating systems that have been developed

worldwide. A comprehensive review of the hundreds of systems could provide a background of such advances. Further research is needed to determine worldwide sustainability and assessing the issues that have more influence on performance. If rating systems integrate performance indicators into models, a more holistic and realistic approach can be implemented to advance sustainable performance metrics. A model in which, sets of building components become building systems and building systems become part of larger systems, allows comprehensively measuring and assessing sustainable performance. This can be a novel approach to the way rating systems become effective tools to reduce impacts of buildings and infrastructure.

Sustainability of Advanced Materials in Construction[☆]

Marco Casini, Sapienza University of Rome, Rome, Italy

© 2020 Elsevier Inc. All rights reserved.

Introduction

The introduction of advanced construction materials is contributing substantially to the improvement of buildings' energy and environmental efficiency throughout their entire life cycle. By introducing new functionalities and improved properties, advanced materials add value to existing products and processes, in a sustainable integrated approach from cradle to cradle. Some of these advanced materials and technologies are already commercially available and have proven cost effective, with payback periods of less than five years. Others are more costly and will require government intervention if they are to achieve a wider market uptake.

Nanotechnology is certainly offering essential innovations for the development and formulation of innovative building products with increased mechanical, physical and chemical properties, with application potential in all technical elements, from structures, to opaque and transparent closures, internal partitions, to systems and appliances.

A new class of highly innovative materials able to perceive stimuli from the external environment and to react immediately to such stimuli, adapting to the changed environmental conditions, so called "smart materials" are finding application in architecture in a high number of products and systems, especially in building envelope components which can most take advantage of their properties of adaptation to different use conditions.

The development of a new generation of multifunctional coatings synthesized by nanotechnology, such as nanocomposite coatings, nanoscale multilayer coatings, super lattice coatings, nanograded coatings, with passive functionality but the capacity to actively respond to changes in their surroundings, is currently a hot technological topic. These coatings will provide key technology for the fabrication of future high-tech 'smart' coatings. Future approaches will focus on tailor-made coatings for specific functions, with particular attention to self healing coatings designed with the ability to repair themselves after chemical or mechanical degradation, based on nanocontainers or nanocapsules that can be filled with inhibitors to protect the substrate from corrosion upon damage or scratching in the coating layer.

In order to foster diffusion of advanced materials, and nanomaterials in particular, a number of barriers still need to be addressed not only related to costs, but mostly to health and environmental concerns basing on reliable and sufficient scientific data. For this purpose, short, medium and long term effects of nanomaterials on health and environment are to be investigated, taking into account the transport mechanism between boundaries as well as levels and type of exposure (direct ingestion, inhalation, dermal intake). The issue of nanomaterials eventually entering the human body is closely related to the form in which they are used in products, with particular concern on their ease of becoming unbound: for instance, nanoparticles covalently bound between them are less likely to become free, as are those firmly embedded in a metal matrix in nanometallic composites (Pacheco-Torgal *et al.*, 2013; Michael *et al.*, 2009; Smith and Granqvist, 2011; Finnish Institute of Occupational Health, 2013). Once detached, free nanoparticles hazard would depend on their mobility, inherent toxicity or potential to carry other pollutants. Environmental concerns also tend to indistinctly merge nanoparticles with the ill-famed ultrafine particles and particulates; while the former are the specific result of an engineering process and serve specific purposes, and thus come in a great variety of sizes, compositions, coatings, the latter are an uncontrolled and unwanted by-product of other activities and processes, and are as such more difficult to assess (Pacheco-Torgal *et al.*, 2013; Michael *et al.*, 2009; Smith and Granqvist, 2011; Finnish Institute of Occupational Health, 2013).

Concluding, most important nanotechnology challenges relate primarily to establishing univocal methods and tools for detecting, characterizing and analyse nanomaterials, to investigating their potential hazard and to assessing the effective exposure. In this picture, regulations shall guarantee high levels of health, safety and environmental protection, while at the same time allowing market uptake of advanced products and fostering innovation and competitiveness in this crucial sector of the industry.

Advanced Materials for Building Sector

Advanced materials are defined as those (both new and deriving from the modification of existing materials) specifically designed to possess new or improved technical properties (structural or functional) or environmental features compared to materials traditionally used to perform the same functions (Featherston and O'sullivan, 2014).

The introduction of advanced materials in the construction industry is contributing substantially to the achievement of energy and environmental efficiency improvements of buildings throughout their life cycle and is leading to profound changes in the whole construction process, from design to implementation. Advanced materials are in fact a key enabling technology for a number of other technologies, and have a key role in enabling advanced/high value manufacturing and in addressing key socio-economic society's grand challenges like climate change and improved efficiency in using resources, supporting and enabling the

Table 1 Advanced materials for architecture: Enhanced and new properties

Enhanced properties	
● Mechanical resistance ● Hardness (abrasion-resistant) ● Shock resistance ● Weldability ● Quick compacting and Curing time ● Corrosion and Oxidation resistance ● UV resistance and control ● Water-protection ● Fire behavior	● Insulation properties ● Thermal conductivity ● Light transmission or reflectance ● Thermal radiation reflectance ● Surface energy ● Electrical conductivity ● Photoelectric effect ● Energy storage
New properties	
● Self-healing ● Air purifying ● Easy to clean ● Anti graffiti and Anti stain ● Scratch-resistant ● Anti-reflection ● Anti-icing and fogging	● Biocidal activity ● Electromagnetic radiation block ● Light emission (LED/OLED, Photol.) ● Chromogenism (dynamic glass) ● Thermotropism (PCM) ● Real-time structural health monitoring

Note: Casini, M., 2016. Smart Buildings: Advanced Materials and Nanotechnology to Improve Energy-Efficiency and Environmental Performance. Cambridge: Woodhead Publishing Limited.

development of new products through radically different and unique functionality, including low carbon technologies. Advanced materials can introduce new functionalities and improved properties, while adding value to existing products and processes, in a sustainable approach oriented to resource conservation, low-impact materials, cleaner production, efficient distribution, green use and maintenance, re-use, re-manufacture, disassembly, recycling and safe disposal. This is particularly advisable with the building sector, characterized by high environmental impacts in terms of resources consumption and waste production (Table 1).

Advanced materials in architecture can be characterized by a fixed, high performance response or by a dynamic behavior in response to external stimuli; the latter characterizes the so-called *smart materials*. These new or improved properties are the result of an engineering process at the nanoscale (nanomaterials) or at larger scale levels (micromaterials or macromaterials). In particular, the nanometric scale offers today higher potential in developing innovative materials and products and in improving performance of existing ones (Pacheco-Torgal *et al.*, 2013; Michael *et al.*, 2009; Smith and Granqvist, 2011). In fact, fundamental properties of matter at the nanoscale level can be significantly different from the same material in its bulk state. These property variations at the nanoscale level can potentially be exploited by embedding these materials with others either at the micro or macro scale level, improving the performance of the bulk material to the desired extent in real-life applications. Advanced materials may be applied by themselves as end products or be integrated in other products or devices, both during the manufacturing process and in the final unit to enter the market.

Concerning the construction sector in particular, most interesting and innovative developments in the field of advanced materials regard nanocomposite materials and coatings (thin films, nano-coatings, nano-paints), thin coverings deposited on a base material in order to provide new or improved surface qualities or appearance. The application of advanced coatings is in fact allowing to improve mechanical, physical and chemical performance of building materials and components, and glazing in particular, by imparting them new properties, both fixed (anti reflection, scratch resistance, etc.) and dynamic (chromogenics, self cleaning effect, shape memory alloys, etc.).

Applications of Nanotechnology

Nanotechnology is bringing many benefits in the construction sector by improving energy and environmental performance of buildings, with application potential in all technical elements, from structures, to opaque and transparent closures, internal partitions, to systems and appliances (Pacheco-Torgal *et al.*, 2013; Sev and Ezel, 2014).

Main applications of nanotechnology are in fact:

- The creation of nanostructured materials by the addition of free or embedded nano-objects within the composition of traditional materials and products, both solid (nano-composites) and liquid (nano-suspensions), such as cement, metals, ceramics, plastics, textiles, paints, adhesives and lubricants, as well as the modification of their internal structure to make it nanocrystalline;
- The use of nanocoatings for the surface treatment of traditional products such as glass, wood, ceramics, textile materials or photovoltaic cells;
- The modification of the surface structure of traditional products to make it nanostructured;

- The creation of new nanoporous materials (nanoporous insulating materials, nano-filters, nano-membranes, etc.);
- The development of nano-devices such as nano electrical and mechanical systems (NEMS).

Several applications are now available for the building industry to increase the mechanical, physical and chemical properties of materials, products and equipment, as well as their durability over time, with the aim of improving environmental comfort, safety, energy efficiency of buildings and at the same time reduce operating and maintenance costs and environmental impacts (Michael *et al.*, 2009; Sev and Ezel, 2014; Sobolev, 2015) (Table 2 and 3).

In particular, the use of nanomaterials in architecture may allow important improvements in:

- Performance of load bearing structures, with the realization of lightweight nanocomposite construction materials (carbon nanotubes, metal-matrix composites, nanocoated light materials, ultra high performance concrete, polymer composites, etc.);
- Thermal and lighting control, with the realization of high performance nanoporous insulating materials (aerogels, VIP, TIM), high reflective coatings (cool roofs), along with low-e, antireflective, passive and dynamic solar control and self-cleaning nano-coatings for glazing;
- Surface characteristics of building elements, with the application of specific nanocoatings or nanopaints (self-healing, air purifying, self-cleaning, antibacterial, anti graffiti and anti stain, photo luminous, scratch-resistant, anti-reflection, anti-icing anti-fogging, fouling-resistant, oxidation and corrosion resistant, UV resistant, fire resistant, etc.);

Table 2 Main building materials properties improved through nanotechnology

<i>Enhanced properties</i>	<i>Nanotechnology</i>	<i>Building products</i>
Durability	Al ₂ O ₃ , SiO ₂ , ZnO particles	Concrete
Mechanical resistance and crack prevention	Polymers, SiO ₂ , FeO and CaCO ₃ particles, CNT Cu particles	Concrete Steel
	CaSO ₄ , SiO ₂ particles	Gypsum drywalls and ceilings
Hardness (abrasion-resistant)	CNT, FeO particles	Concrete
Shock resistance	V, Mb particles	Steel
	Al ₂ O ₃ particles	Concrete
Weldability	CuO, Ca, Mg	Steel
Formability	Nanopolymers	Concrete
Quick compacting	TiO ₂ , particles, CSH nanocrystals	Concrete
Curing time	TiO ₂ , CaCO ₃ particles, CSH nanocrystals	Concrete
Corrosion resistance	SiO ₂ particles	Paints
	Al ₂ O ₃ , SiO ₂ coating	Steel
Oxidation resistance	CuO particles	Steel
UV resistance	ZnO, CeO ₂ Coating	Wood
Moisture resistance	C ₆ H ₁₀ O ₅	Concrete
Water-protection	Fatty acids coating	Wood
	SiO ₂ particles	Concrete
Fire behavior	SiO ₂ particles	Glass
	TiO ₂ , particles	Concrete
Insulation properties	SiO ₂ Aerogel, SiO ₂ particles	Insulating materials
	Hydro-NM-Oxide particles	Paints
Thermal conductivity	Carbon nanotubes	Polymers and plastics
	Metal oxides coating	Glass
Visible and Near infrared Light transmission or reflectance	VO ₂ , FeO, SiO ₂ , ITO coating	Glass
	Nanoceramics coating	Solar films
UV control	TiO ₂ , ZnO coating	Coating
Thermal radiation absorption or reflectance	Ceramic Nanoparticles	Paints
Adhesion	SiO ₂ or SiH ₄ particles	Adhesives
Rheology	SiO ₂ particles	Paints
Surface energy	SiO ₂ particles	Paints
Electrical conductivity	Carbon nanotubes	Polymers and plastics
Photoelectric effect	Quantum dots, Graphene, CNT	Thin film solar cells
	TiO ₂ particles	DSSC
	Si particles	Silicon solar cells
Energy storage	Graphene, carbon aerogel, CNT	Batteries, capacitors
	Zeolite particles	Wood
Friction	Fullerene	Lubricants
	Ceramic coating	Steel

Table 3 Main new building materials properties provided through nanotechnology

<i>New properties</i>	<i>Nanotechnology</i>	<i>Building products</i>
Self-healing	Nanopolymers	Concrete, gypsum
Air purifying	TiO ₂ , ZnO coating	Ceramic tiles, Glass
	TiO ₂ particles	Paints, Concrete
	Zeolite particles	Gypsum drywalls, ceilings, Plaster
Easy to clean	SiO ₂ coating	Glass
Anti graffiti	TiO ₂ , SiO ₂ coating	Concrete
Anti stain	TiO ₂ , SiO ₂ coating	Concrete
Scratch-resistant	Al ₂ O ₃ coating	Ceramic tiles and sanitary ware
	SiO ₂ particles	paints
Anti-reflection	SiO ₂ coating	Glass
Anti-icing	CNT	Glass
Anti-fogging	TiO ₂ coating	Glass
Fouling-resistance	TiO ₂ , Ag coating	Ceramic tiles, Glass
	TiO ₂ particles	Paint
Biocidal activity	Ag, ZrO ₂ CuO coatings	Ceramic tiles and sanitary ware
	Ag particles	Paints
	Ag, Cu, Zn particles	Wood
Electromagnetic radiation block		
Light emission	Graphene	OLED lighting
	Quantum dots	LED lighting
Artificial photosynthesis	TiO ₂ particles	Hydrogen production
Dynamic response	Semiconductive metal oxides	Dynamic glazing
Real-time structural health monitoring	CNT	Concrete

Note: Casini, M., 2016. Smart Buildings: Advanced Materials and Nanotechnology to Improve Energy-Efficiency and Environmental Performance. Cambridge: Woodhead Publishing Limited.

- Energy efficiency in lighting (LED/QLED, OLED);
- More efficient and integrated renewable energy systems (polymeric, dye sensitized, quantum dots, thin-film and multi-junction PV solar cells, fuel cells, etc.);
- Building and environmental monitoring and control, with the realization of nano embedded sensor, actuation and control systems (NEMS).

Within these construction materials, elements and systems, nanomaterials can be integrated in the form of solid nanocomposite materials, solid materials enhanced with nano-coatings or characterized by nanostructured surfaces, nanoporous materials and fluid nanodispersion as nanopaints, nanoadhesives or nanolubricants.

More specifically, in the nanocomposite class of materials one or more phases at the nanoscale dimensions (3-D, 2-D, 1-D) are embedded in a polymeric, metallic, or ceramic matrix. Nano-objects embedded in the matrix (usually a few percentage by weight) can be made of various primary materials and their addition can provide the material with unique and enhanced properties compared to conventional composite materials.

Nanocoatings, or nanofilms, are thin films which incorporate nanomaterials, or have a thickness at the nanoscale (< 100 nm), deposited on a substrate material to enhance its surface properties (durability, abrasion or corrosion resistance, electrical, magnetic or optical behavior, etc.) without having to alter its entire mass. Multiple nanoscale layers can be built up to form multilayered or laminate nanostructures. Using thin nano-based coatings is a very convenient way of exploiting the remarkable properties of nanomaterials without the high production cost associated with manufacturing large components fully out of nanocomposites. This gives them one of the greater overall market potentials for any kind of nano-based product or device. Among nano-objects used as a standalone end product, one of the most interesting and promising ones is certainly the graphene, aptly surnamed “wonders material”.

Concrete

Nanotechnology application to the concrete industry allows to obtain products with unprecedented performance regarding both mechanical properties and durability over time, along with improvements in the construction process (ease of mixing, rate of setting, workability etc.) and a reduction of carbon emissions of cement manufacturing (reduced kiln temperatures and durations that occur during processing) (Hossain and Rameeja, 2015; Leone, 2011). Environmental benefit potential is indeed very high, as cement production generates over 1.6 billion tons of carbon worldwide, more than 8% of total carbon emissions. Concrete also accounts for more than two thirds of construction and demolition waste with only 5% currently recycled (Pacheco-Torgal *et al.*, 2013).

Nano-enhanced concrete products may be both nanocomposites, as cement blend added with nanoparticles to enhance its properties, and nano-coated for modifying its surface properties and its interaction with the environment.

Nanocomposite concrete can become impermeable through the addition of inorganic solutions that during curing fill its capillary void with nanocrystals, and can cure much faster due to silicate hydrates nanoparticles that accelerate hydration process without requiring energy intensive treatments such as hot steam or hazardous additives. Addition of TiO_2 nanoparticles makes it photocatalytic, allowing for improved durability, self cleaning action and also air purifying effect, with the added benefit of improved fire behavior. Regarding mechanical performance improvement, currently available Ultra High Performance Concrete (UHPC), added with metal and silicon oxide nanoparticles, require much less material to achieve the same structural strength compared to traditional products thus allowing for a much reduced environmental impact with 6 times reduction in raw materials, 50% reduction in GHG emission and 40% reduction in manufacturing energy. Carbon nanotubes addition is being researched and will allow a 90% reduction in material use.

Concerning concrete nanocoatings, anti-graffiti and anti-stain effects can be achieved by the application of SiO_2 nanoparticles solutions to form a nanothin layer of glass on its surface, preventing moisture or graffiti paint from penetrating the pores and dirt or algae from attaching to the surface. TiO_2 coatings impart self healing and air purifying effect as well.

Metals

Nanotechnology allows for improving a number of properties in all metal applications, being them structural steel, metal piping or interior/exterior surfaces (Michael *et al.*, 2009). The properties of many common metals can be greatly enhanced by the addition of relatively small amounts of nanomaterials – Normally in the form of nanoparticles, nanowires, and nanotubes – As well as by the application of specific nanocoatings.

High performance steel for most demanding applications, such as bridge supporting cables or precast concrete, undergo specific manufacturing processes to reduce their crystalline structure to the nanoscale (nanostructured steel).

Nanocomposite steel develops instead improved properties concerning oxidation resistance and workability (addition of copper nanoparticles), fatigue resilience (addition of vanadium and molybdenum) and welding behavior (through calcium and magnesium particles).

Several nanocoatings allow for improved corrosion resistance thanks to alumina and silica nanoparticles, or employ polymer nano dispersions to promote acrylic coatings adhesion. These nanocoatings constitute more durable and environmentally friendly alternatives to traditional chromating baths. Steel used in highly hygienic environments such as healthcare facilities, as well as medical grade tools, develops an anti microbial effect with the addition of silver or copper nanocoatings. Metal employed in mechanical gears can greatly reduce surface friction through the use of nanoceramic coatings. Finally Architectural metal surfaces can also be protected with anti scratch coatings based on the addition of aluminium oxide nanoparticles (Al_2O_3) in 1%–5% concentration in aqueous coating systems, acrylate dispersions or aliphatic polyurethane dispersions.

Plastics

Plastics and polymers (thermoplastics, thermosets and elastomers) can also take advantage of the benefits of nano-objects integration (polymer-matrix nanocomposites) or nano-coatings deposition on their surface (Michael *et al.*, 2009).

Many kinds of nanofillers (silicas, clays, carbon nanotubes, carbon blacks) are suitable for integration in polymer nanocomposites. The use of a small quantity of nanoparticles, nanotubes or nanoplates – A few percentage by weight – As a reinforcing second-phase material can in fact dramatically alter the properties of the different polymers. For instance, both strength and modulus of elasticity values can be either increased or decreased depending on the polymer host and the nanoscale reinforcing phase: materials such as polystyrene reinforced with silica nanoparticles show an elastic modulus increase while carbon nanoparticles can increase toughness and wear resistance.

Carbon nanotubes can sensibly increase compression strength if dispersed in thermoset epoxies (in the 30% range), with only 0.5%–2.0% wt proportions. Many types of widely used thermoplastics such as polycarbonates can also be added with CNTs with the aim of increasing compressive and impact strength, toughness, elongation, and other properties.

Regarding nano-coatings application to plastics, it is challenging to carry out because of polymers' organic nature and low heat resistance. An effective, transparent scratch resistant coating (+ 55% abrasion resistance) has however been obtained by chemically growing zirconia nanoparticles on top of the polymeric surface.

Ceramics

Ceramic materials in architecture include tiles both for interior and exterior application as well as sanitary ware. All of these applications may benefit from nanotechnology, improving their durability and ease of maintenance characteristics or giving them new properties altogether (Michael *et al.*, 2009). Through the application of nanocoatings, ceramic surfaces can repel dirt and water by becoming superhydrophobic (coatings with SiO_2 nanoparticles that fill surface pores and give an ultra-smooth surface) or superhydrophilic and photocatalytic (TiO_2 coating). SiO_2 coatings also provide anti scratch properties without impeding gloss. Nanosilver coatings finally provide a biocidal effect both on ceramic tiles and sanitary ware.

Glazing

Glazing is indeed one of the fields in which nanotechnology is having the widest impact, with several nano-enhanced products already on the market with much improved performance or altogether new properties. In architecture, glass is mostly employed to achieve natural lighting of interiors, and nanotechnology allows to realize extremely thin coatings with multiple functions that do not hinder excessively its most sought after characteristic, visible light transparency. In particular, nanocoatings may increase glass transparency through anti-reflective effect (multiple nanosized polymer layers with different refractive angles) or by preventing dirt build-up by making its surface superhydrophobic (nanosilica coatings) or superhydrophilic and photocatalytic (TiO_2 coatings). These high transparency levels ensure maximum daylighting levels and, in the case of building integrated photovoltaics, maximum efficiency in harvesting solar energy. SiO_2 nanoparticles intumescent interlayers also allow for fireproof glazing without loss of transparency. Glass fogging as well as snow or ice accumulation can be prevented by self heating glass, obtained by metal or carbon nanotubes coatings that make its surface electrically conductive.

From the energy efficiency point of view, nanocoatings are widely used to improve glazing thermal transmittance (low-e coatings using metal oxides nanoparticles) or filter and absorb UV or NIR radiation (silicon or metal oxides nanocoatings, nanoceramic solar films), avoiding heat loss in winter and excessive heat loads in summer months. In addition to static solar protection glazing, are now available dynamic solar control coatings that can vary their transparency to visible or IR light reacting passively to light (photochromic glass) or heat (thermochromic glass). Electrochromic glazing allows active dynamic control of light and heat transmission thanks to a thin film coating comprised of several extremely miniaturized conductive layers.

Insulating Materials

Nanotechnology can be also used to create new advanced high performance insulating materials able to provide exceptional heat flow resistance performance thanks to their nanoporous structure achieved via sol-gel processing (silica aerogel), also in vacuum applications (VIP) or additionally providing solar radiation transparency (TIM) (Casini, 2016).

Due to their low thermal conductivity ($\lambda < 0.02 \text{ W m}^{-1} \text{ K}^{-1}$) it is possible to obtain high thermal resistance values of building envelope with extremely thin insulating layers (less than a third compared to conventional insulating materials). These products are thus particularly suitable for the correction of thermal bridges and for energy retrofit of existing buildings, especially of historic buildings subjected to architectural constraints, and in all cases in which it is necessary to increase energy efficiency and comfort with minimum space loss.

Near infrared reflecting coatings such as nanopaints can also be used for roof and wall applications in order to reduce the summer overheating and Urban Heat Island Effect (Cool roofs).

Finally, nanomaterials addition can significantly alter the thermophysical properties of heat storage materials, especially in phase change materials (PCMs) for latent thermal energy storage (LTES) applications. There, the incorporation of specified proportions of nanomaterials can increase thermal conductivity, accelerate freezing and melting rates, improve thermal stability, and ensure thermal reliability over time.

Adhesives

Most used adhesives today are based on elastomers, thermosetting or thermoplastic polymers and other materials, and current research on increasing performance and ease of application is being spurred by the advent of nanoscience and nanomaterials.

Nanomaterials as now are mostly added to improve rheology characteristics, such as viscosity and anti sagging, allowing for thinner, more uniform adhesive coating applications: most used in this regard are nano-sized silicates. The inclusion of metal or carbon nanoparticles such as iron oxide allows to obtain electrical conductive adhesives that allow electricity transfer in electronic applications and electromagnetic induced curing (Michael *et al.*, 2009).

Nanoscience is also taking inspiration by naturally occurring nanosized structures to mimic their behavior: in this sector, research has focused on the adhesive ability of mussels and geckos. Regarding the gecko, it has been observed that its excellent clinging ability stems from the nano structured surface on its feet, which feature many small hairs each split in even smaller hairs at the end, called satae. Each of these is covered by cuplike spatulae 200 nm in size, which radically increase the contact area between the hairs and the surface, achieving up to billions contact points that take advantage of both Van der Waals forces and capillary action. Mimicking this behavior shall allow for powerful and reversible adhesive action, and this is carried out by nanostructured surfaces with patterns akin to those of the gecko's soles, such as PMMA nanopillars arrays obtained by electron beam lithography or CNTs. Promising results were obtained, but a decrease of adhesion in wet environments was noted. Research on wet adhesion turned instead to mussels and their ability to reversibly cling to virtually any underwater surface. It was discovered that these unique capability stems from a specialized protein secretion, rich in the amino acid L-Dopa, which is known to provide underwater adhesion and self-healing capabilities. This was mimicked in engineered polymers with an analogue synthesized protein, obtaining an high performance underwater glue applicable in thin films and 10 times more effective than conventional wet adhesives (Kollbe Ahn *et al.*, 2015). By coating gecko inspired nanopatterns with this mussel-inspired adhesive, exceptional, reversible performance both in dry and wet environments was finally achieved.

Paints

Nanotechnology influence in paints sector has been successful, and the addition of nanoparticles in their solution has led to the development of a whole range of innovative and high performing nanodispersed products (Michael *et al.*, 2009). In particular, nano dispersions can show improved characteristics of rheology, settling and viscosity, improving paints' behavior during application, through the addition of nanoclays and silica or aluminium nanoparticles. Photocatalytic paints include dispersed TiO₂ nanoparticles to achieve a self cleaning, anti fouling and air purifying effect if exposed to UV rays, while other self cleaning paints instead exploit the lotus effect, caused by a bumpy surface nanopattern which is small enough to prevent water drops from attaching, causing them to roll away taking dirt particles with them. Interior environments healthiness can be raised by biocidal paints, comprised of nanodispersed silver particles that prevent bacteria and microorganisms from developing. Similarly, metal nanoparticles or carbon nanotubes can make surfaces antistatic or block unwanted electro magnetical radiation.

Lifetime and colour fastness of organic paints exposed to UV degradation can be increased by the addition of metal oxides nanoparticles such as zinc, cerium or titanium, and transparent protective paints (clear coats) for furniture and wood protection can increase their scratch and abrasion resistance with no gloss alteration by the inclusion of silica nanoparticles. Furthermore, interesting colour effects can be achieved on any surface by adding multiple polymer nanolayers with different refractive angles, this varying the wavelength and colour of reflected light according to the viewer position (dichroic effect). Lastly, nanoparticles addition to paints can improve their reflectance to solar radiation for cool roof applications.

Lighting

The energy efficiency of lighting systems is very important due to their high electrical consumption in both residential and tertiary buildings. Last generation incandescent lamps, still widely used in existing buildings, were characterized by low efficiency and heat release and overheating issues, especially in hot climates during summer months.

Solid state lighting technologies such as Light Emitting Diodes (LED) have allowed to greatly improve energy efficiency of lighting systems, superseding at the same time also fluorescent lamps. However, despite their high energy efficiency, actual emission wavelengths that can be generated remain limited and not easily adjustable, and the production of full-spectrum "white light" is still equally problematic since it requires a final adjustment via the addition of phosphors with still unsatisfactory results.

In this picture, existing LED technologies can be widely improved with the integration of a variety of nanostructures, with several beneficial effects including:

- Increasing light extraction or out-coupling from LED chips;
- Enhancing luminescent output by increasing emitters' surface areas;
- Improving the efficiency of injected electrons by using nanostructured electrodes;
- Improving light control by using novel nano-phosphors;
- Exploiting surface fluorescence of quantum dots.

Among these, quantum dots networks integration in LEDs is particularly interesting, paving the way for highly efficient and performing innovative QLEDs. Quantum dots (QDs) consist in nanocrystals of semiconductor materials such as germanium or silicon, which electronic and luminous properties are directly related to their diminutive size. Advantages include high efficiency, better control of emitted light as well as further miniaturization of form factors. Concerning light control, the actual emitted wavelength, thus the colour, does not strictly depend on the semiconductor material as in conventional LEDs, but can be finely tuned by acting on the nanocrystals. Nanoparticle size in fact dictates energy separation levels, which in turn vary the wavelength of emitted photons. This way, precise colour emittance to match specific needs, even in the case of full spectrum white light, can be achieved by directly mixing the right kinds of constituent blue, green and red emitting quantum dots. Quantum dots also benefit from a more convenient manufacturing process: nanocrystals can be grown in large quantities with colloidal approaches, instead of being precisely shaped and cut from germanium or silicon wafers as in macroscale semiconductors.

Further research on LEDs manufacturing by using QDs regards instead the use of carbon made QDs, so called Carbon Dots (CDs); these can even be produced from waste bread and alcohol-free sugar beverages, allowing a further reduction in raw materials costs and environmental impacts (Casini, 2016). Design flexibility potential is also exceptional, as quantum dots may be incorporated into various types of polymeric materials, rigid, flexible and even transparent, through depositing, casting or painting processes. Moreover, potentially longer operating life and improved stability make QLEDs effectively competitive with the other breakthrough evolution in lighting technology, organic light emitting diodes (OLED).

Smart Materials

"Smart materials" are a new class of highly innovative materials able to perceive stimuli from the external environment and to react immediately to such stimuli, adapting to the changed environmental conditions (Schwartz, 2009; Ritter, 2007). This reaction is usually caused by a change in the values of the surrounding energy field (change in potential, electrical, thermal, mechanical, chemical, nuclear or kinetic energy) that triggers in the material a chemical reaction, a change in the molecular or crystallographic

Table 4 Smart materials classification

<i>Type of smart material</i>	<i>Environmental stimulus</i>	<i>Reaction/effect</i>
Property changing materials		
Thermochromics	Temperature difference	Colour change
Photochromics	UV radiation	Colour change
Mechanochromics	Deformation	Colour change
Chemochromics	Chemical concentration	Colour change
Electrochromics	Electrical tension	Colour change
Liquid Crystals	Electrical tension	Colour change
Suspended particles	Electrical tension	Colour change
Photocatalytics	UV radiation	Chemical reaction
Thermotropics	Temperature difference	Phase change
Electrorheological	Electrical tension	Viscosity change
Magnetorheological	Magnetic field	Viscosity change
Shape memory	Temperature difference	Crystalline phase change
Energy exchanging materials		
Electroluminescents	Electrical tension	Visible light emission
Photoluminescents	Radiation	Visible light emission
Chemiluminescents	Chemical concentration	Visible light emission
Thermoluminescent	Temperature difference	Visible light emission
Photovoltaics	Solar radiation	Electrical tension
Bidirectional energy exchanging materials		
Piezoelectric	Deformation	Electrical tension
Thermoelectric	Temperature difference	Electrical tension
Pyroelectric	Temperature difference	Electrical tension
Electrochemical	Chemical concentration	Electrical tension
Electrostrictive	Electrical tension	Deformation
Magnetostrictive	Magnetic field	Deformation

Note: Casini, M., 2016. Smart Buildings: Advanced Materials and Nanotechnology to Improve Energy-Efficiency and Environmental Performance. Cambridge: Woodhead Publishing Limited.

structure, an alteration of the voltage ranges, the absorption of a proton, and other phenomena. The effects may show in phenomena such as a change in colour, a change in volume, a change in the distribution of stress and deformation or a change of the refractive index.

Compared to traditional materials, smart materials are characterized by the following properties (Featherston and O'sullivan, 2014):

- Immediacy, as they respond to stimuli in real time;
- Transiency, as they respond to multiple environmental states;
- Self-actuation, as the ability to react is internal to the material, rather than external;
- Selectivity, as the reaction is discrete and predictable;
- Directness, as the reaction is internal to the event triggering it.

Depending on the type of reaction to the external energy field, smart materials are generally divided into Property Changing Materials and Energy-exchanging Materials (Table 4). Smart materials may come in the micrometer, micrometer or nanometer scale (smart nanomaterials).

The ability of smart materials to produce a useful effect in response to external stimuli makes them greatly interesting for their application in the fields of design and architecture in particular, both characterized by changing and dynamic needs (Table 5). Both types may also find application as sensors or actuators in smart devices or systems directly integrated into the building body.

As defined above, "smart materials" are qualified based in their "smart" behavior, as in a dynamic response which includes all the properties mentioned above. However, the term "smart" is still vague, so in general terminology is often used more widely to describe materials or behaviors with high or unique performance and properties, for instance easy to clean surfaces or self healing materials, even if they don't exactly fit in the "smart materials" category.

Property Changing Materials

The first category includes materials which autonomously and reversibly change one of their mechanical, chemical, optical, electrical, magnetic, or thermal properties in response to a stimulus. They include different types of materials such as chromogenic materials (thermochromics, photochromics, mechanochromics, chemochromics, electrochromics, liquid crystals and suspended particles), phase change materials, photocatalytic materials, electrorheological and magnetorheological materials, as well as shape memory alloys.

Table 5 Main applications of smart materials in the building sector

<i>Requirement class</i>	<i>Specific need</i>	<i>Smart material</i>
Controlling solar radiation transmittance through the building envelope	Control of spectral absorbance and transmittance of transparent closures	Electrochromic glass Photochromic glass LCD glass SPD glass
	Dynamic control of screening systems	External radiation sensors (photovoltaics) Interior daylighting sensors (photovoltaics) Actuators (shape-memory alloys)
Controlling heat flows through the building envelope	Control of thermal conductivity of building envelope materials according to climatic conditions	Thermotropic materials
Controlling temperature of interiors	Increase of thermal capacity of closures and internal partitions	Phase change materials
	Placement of heat sources outside the environment	Optical fibre systems Thermoelectric materials
Controlling air quality	Increase the lighting/heat ratio	LED/OLED Photoluminescent materials
	Monitoring of CO ₂ and pollutant agents	Sensors
Producing energy from renewable sources	Air purification	Photocatalytic materials
	Conversion of environmental energy into electric energy	Photovoltaics Piezoelectric materials
Optimizing lighting systems	Environment lighting monitoring	Photovoltaics
	Interiors daylighting monitoring	Photoelectric materials
Optimizing HVAC systems	Interiors occupancy monitoring	Optical fibres Electroluminescent materials
	Lighting sources placement	Pyroelectric materials
Controlling structural vibration	Temperature monitoring	Hygrometers
	Humidity monitoring	Photoelectric materials
	Interiors occupancy monitoring	Biosensors
	Monitoring of CO ₂ and pollutant agents	Thermoelectric materials
	Heat sources and storage placement	Phase change materials
	Eulerian buckling control	Piezoelectric materials
	Inertial damping control	Magnetorheological materials
		Electrorheological materials
		Shape-memory alloys
	Stress monitoring	Optical fibres

Note: Casini, M., 2016. Smart Buildings: Advanced Materials and Nanotechnology to Improve Energy-Efficiency and Environmental Performance. Cambridge: Woodhead Publishing Limited.

To date, these materials already found application in architecture in a high number of products and systems, especially in building envelope components which can most take advantage of their properties of adaptation to different use conditions. In particular, property changing materials are used:

- In transparent closures for dynamic control of solar radiation (chromogenic materials);
- In closures and in internal partitions to increase their thermal inertia (phase change materials);
- In mortars, paints or coatings of external and internal surfaces of the building in order to achieve a self-cleaning and at the same time atmospheric air purifying effect (photocatalytic materials).

As for transparent closures, these are certainly the most interesting application field of property changing materials, both for new constructions and for existing buildings. The need to combine vision and daylighting through glazed closures with incoming solar radiation control via conventional fixed sun screening systems has led to compromise solutions, skewed toward only one of these requirements and unable to guarantee the best operation along all four seasons. The integration of chromogenic materials in transparent closures instead allows to adapt the characteristics of light transmission and solar shading to external conditions, either with passive systems, completely self-sufficient and not user-controllable (such as thermochromic and photochromic glazing), or with active systems, freely configurable by users or by an integrated management system with the trade off of needing an electrical power supply (electrochromic, LCD, SPD glazing).

Equally interesting is the application in opaque closures and partitions of phase change materials (PCM), capable of reacting to changes in temperature with a state transition able to exponentially increase their thermal capacity. Available in different shapes

and packages (macroencapsulated panels, beads, bags, or microencapsulated in bulk form or integrated in various components such as bricks, gypsum, mortar and plaster), they are used as components in low inertia building systems such as lightweight opaque closures and interior partitions or translucent closures.

As regards photocatalytic materials, they have been finding large use in the building industry since the early 1990s: semiconductor metal compounds such as zinc oxide (ZnO), tungsten oxide (WO₃), cadmium selenide (CdSe) and titanium dioxide (TiO₂) by reacting to ultraviolet (UV) radiation lead to the formation of high reactive agents with the ability to oxidize and decompose many types of bacteria, organic and inorganic materials by photo-induced redox reactions of adsorbed substances.

Among photocatalytic construction and building materials, titanium dioxide (TiO₂) is the most widely used photocatalyst for its numerous advantages: it is chemically stable, safe, widely available and relatively inexpensive; it presents a higher photocatalytic activity compared with other metal oxide photocatalysts; it is compatible with most traditional construction materials, such as cement, without changing any original performance; it is also effective under weak solar irradiation in ambient atmospheric environment (Chen and Poon, 2009). Applied to the construction industry TiO₂ has allowed the development of paints for external or internal applications, mortars and cements, tiles and other construction products able to perform due to solar radiation a self-cleaning and depolluting action. TiO₂ induced photocatalysis is a promising technology also for self-cleaning applications. Besides its photocatalytic properties, TiO₂ demonstrates an intrinsic photo-induced surface super-hydrophilicity. In fact, differently from other photocatalytic materials, when water is adsorbed on this semiconductor material irradiated by UV light, it spreads forming a thin film instead of grouping in water droplets. When water is rinsed over the surface, contaminations like oil can be washed away.

Photocatalytic properties also characterize tungsten trioxide nanoparticles (WO₃). Tungsten based Renecat photocatalytic agent, manufactured by Toshiba, claims superior performance compared to TiO₂ regarding deodorant and antibacterial effect even with fluorescent or white LED artificial light, making it viable for interiors use. Furthermore it can also be applied on polymeric surfaces, such as PMMA or polycarbonate glazing, if provided with an inorganic binder.

Finally, shape-memory alloys can have interesting applications in the construction of buildings and architectural elements able to self-adapt to ambient temperature or assembled with the only supply of electricity or heat. When an object made of shape memory alloy such as nitinol (nickel titanium – NiTi) is deformed from an initial shape to a new one, it will keep this last configuration. If however heated to a certain temperature, either directly or by electric current, it will revert to its initial shape without any mechanical aid, as if it remembered its base configuration. This unique shape-memory effect is caused by the internal phase changes that the material undergoes during the deformation and shape return processes (from martensite to austenite upon heating and vice versa upon cooling). This process is generally reversible, although some shape deterioration over time may occur if the bending and heating are not carefully controlled. Shape memory alloys are applied in several industry sectors: they are used in simple release mechanisms to reduce the need for moving parts, and shape memory superelasticity allows metals to undergo extreme deformation (up to 8%) without consequences, and is for instance used in high end eyeglass frames. Shape-memory have also been developed in the form of rigid plastics or relatively porous foams, with a wide application scope, including self unrolling surfaces, knots that tie themselves for medical applications or consumer customizable furniture.

Energy-Exchanging Materials

The second category of smart materials instead includes those materials capable of converting more or less reversibly an input energy into another form of energy in accordance with the first law of thermodynamics. They include photovoltaic, luminescent (LED, OLED), piezoelectric, thermal and pyroelectric, electrostrictive and magnetostrictive materials. Main applications of energy exchanging materials in construction certainly concern photovoltaic materials and electro and photoluminescent materials.

Photovoltaic materials enable the production of electrical energy by transforming the incident solar radiation (photoelectric effect). Photovoltaic technology has reached the third generation of solar cells and boasts decades of applications. Research trends today are focusing on the development of processing techniques that would allow the production of high efficiency, low cost and high yield solar cells made of CIGS, CdTe and organic materials (polymer composites and dye sensitized solar cells). Further promising smart technologies for solar energy capture regard the direct conversion of light waves into DC current. Using multiwall carbon nanotubes and tiny rectifiers fabricated onto them, researchers have recently demonstrated the first “optical rectenna”, a device that combines the functions of an antenna and a rectifier diode to convert light directly into electricity, for now with a conversion efficiency of 1% but with good growth potential (Sharma *et al.*, 2015).

Regarding luminescent materials, they are commonly classified as chemiluminescent, electroluminescent, or photoluminescent according to the excitation energy source, albeit light emission can depend other energy mechanisms (such as friction).

Electroluminescent materials are the basis of the solid-state lighting technology used in Light Emitting Diodes (LED) systems, characterized by high efficiency, small size of light sources and application versatility. A new generation of solid state lighting is constituted by quantum dots light-emitting-diodes (QLEDs), made of quantum dots networks. These work similarly to conventional LEDs but show greatly improved functionality and even wider applications.

Photoluminescent materials are capable of absorbing solar light and re-emit it at a different wavelength in the visible spectrum (fluorescent and phosphorescent materials).

Lastly, as regards the piezoelectric effect, it consists in the property of some crystalline materials to polarize when subjected to a mechanical deformation (direct piezoelectric effect), generating a potential difference, and at the same time to deform in an elastic

manner when traversed by electrical current (inverse piezoelectric effect). The piezoelectric effect occurs only along one direction and deformations associated with it are the order of nanometers. Many common devices, including doorbells, speakers and microphones or quartz watches are based on piezoelectric technologies. Piezoelectric elements are also the key of recent proposals for harvesting energy from pavements and roads by exploiting kinetic stress.

Conclusions

Thanks to the huge progress in the field of materials science, technology solutions available today for buildings allow to harmonize the architectural quality with the new challenges of sustainability, offering new opportunities in terms of greener and smarter buildings. The goal of reducing energy consumption and environmental impacts in the use and maintenance phases of new and existing buildings is in fact being facilitated by the progressive introduction of advanced nanotechnology materials, which physical and mechanical properties greatly exceed those of traditional materials, and of active components and devices, so-called “smart materials”, able to modify their own characteristics in relation to different operating conditions determined by the climatic agents or by the users, allowing the realization of dynamic building elements and opening up important new possibilities in the way of design and renovate buildings in the twenty-first century.

Sustainable Architecture, Alternative Concepts and Waste Reduction

Abraham George, Indian Institute of Technology Kharagpur, India

© 2020 Elsevier Inc. All rights reserved.

Concepts of Sustainability

Sustainable design and development is defined as; “design and development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (World Commission on Environment and Development, 1987). The need for finding long-term solutions that warrant continuing human existence and well-being is far more compelling in these days of depleting resources and catastrophic climate change, than in the former days (Papanek, 1995). The need for waste reduction is of prime importance since materials saved is equivalent to materials produced. Though, it is Green and sustainable that are the catch words of design, in the contemporary helpless climatic scenario which is worsening over the passage of time, these have also created ample ambivalence and confusion. Thanks to the urgency of the situation, debates on the terms green, sustainable or ecological architecture has become almost meaningless, but the kernel matter lies with addressing the needs of harmonic and ecologically sustaining design and development, emphasizing on material waste reduction, that would assure the future of the earth with all its myriad of living and nonliving systems.

During a building's actualization process, its construction affects the local and global environments by way of interconnected human activities and natural processes. In the beginning stages, site development and construction influence the local ecology and its characteristics. The influx of heavy construction equipments and personnel onto a building site and various processes involved, disrupt the local ecology to a considerable extent, though it may be improved as the construction gets expedited (Ngowi, 2001; Spence and Mulligan, 1995). Needless to state that manufacture, transport and procurement of materials at various stages never fail to leave their impact on the global environment. Completed buildings require resources and energy in various forms for their useful performance. These, in turn, give rise to pollution and add to the mammoth problem of waste and environmental degradation which inflicts long-term impact on the environment. For instance, fuels and water used by its inhabitants produce toxic gases and sewage. Similarly, the process of extracting, refining, and transporting all the resources used in building operation and maintenance also has negative impacts on environment. Further, construction waste produced poses a great problem which could be avoided if creatively looked at it. This needs careful planning, dimensional; Modular, coordination and management that would result in the resource waste reduction.

Global ecosystem is essentially made up of three group namely inorganic substances, living organisms, and human beings (Çelebý, 2003). Built forms contribute to the compounded impact of architecture on global ecosystems. It is therefore, important to study the impact of built forms on the totality of the environment, throughout various stages. Developments should be facilitated taking into consideration the entirety of the systems; *resource, energy and transport etc., and the myriad of population of the Nation*, along with the specific characteristics of the region being developed. Although the general rule is to use the available materials at closer proximity to the site, it may not work out to be feasible when it comes to new and appropriate expressions sought by architects.

Though, it is *green* and *sustainable* that are the catch words, an examination of the meaning of ‘sustainable’ is required to avoid the avoidable confusion these words tend to generate, knowingly or otherwise (Andrew, 1992). Sustainable architecture describes the fact that ‘we receive what we need, from the nature’. Sustainable architecture, then, is a *farsighted positive response to awareness that everything we need is received from nature*, not a prescriptive formula just for our survival (Bergen et al., 1997). In other words, the goal of sustainable design is to find architectural solutions that warrant the well-being and coexistence of constituent groups (Kim and Rigdon, 2000). Therefore, a conceptual approach to framework is to be developed in order to meet the goal of well-being and coexistence together with resource waste reduction in an effort to attain sustainability. Three fundamental concepts of the framework proposed are; *Objectives, Strategies and Achievement*. These relate to the environmental responsibilities, creating environmental awareness, explaining the building ecosystem and designing sustainable built forms with care and efficiency, for the future (Çelebý, 2003).

Why Sustainable Architecture

Sustainable architecture aims at the *Protection of Resources – (PR)*, is the primary response to the awareness which influences all the following stages. Architects have to be mindful of the efficiency of forms, flexibility in designs and potential to reuse the components or the building itself on a later date. *Life Cycle Design – (LCD)* and *Livability Design – (LD)* facilitate healthy habitation for humans. Protection of natural resources is proposed at the inception stage of building process, to be achieved through the reduction and reuse; *direct reuse or recycling*, of the physical resources involved (Çelebý, 2003). While *Life Cycle Designs* provide a methodology for analyzing the building process and its impact on the environment in an effort to decide on the effectiveness of designer's choices, *Livability Design* focuses on the interactions between human beings and the natural environment (American Institute of Architects, 1996) (Fig. 1).

A sympathetic attitude from architects is extremely important as they interact primarily with users and environment in the establishment of a harmonious, healthy and sustainable built environment. Hence, understanding the above objectives which

Fig. 1 Framework of concepts and strategies for sustainable architecture.

embodies a unique set of intentions is important to develop a more thorough understanding of the designer's positive interaction with the environment. The genesis of a project leading to its geographic location is one of the extremely important phases in the effort to reduce the load on infrastructure and consumption of resources and generation of waste and pollution. Locating a sustainable built form far away from the supporting or depending facilities would generate unnecessary traffic perils associated with commutation which is avoidable. Moreover, developing countries like India has the major part of 60% of its population living in rural areas. Appropriately rated economic magnets like Special Economic Zone – (SEZ), IT parks, industries or the like may be effectively used in order to achieve balanced development in rural areas which would retard the unhealthy migration to already congested urban areas. Moreover, as a strategy, develop automobile free, 'walk to work' rural or peri-urban communities, self-sufficient in water and energy requirements, equipped with appropriate waste management systems. Such sustainable communities may be the hubs that are effectively connected to others by means of high speed, ecologically friendly mass transit systems.

Protection of Resources – (PR)

It is the responsibility of an architect to reduce the use of nonrenewable resources in the construction and operation process of buildings in an effort to protect the resources and to preserve these for the future generations (Kua and Lee, 2002). Natural and manufactured resources, as is seen, are in a continuous flow in and out of any building which begins with the production of building materials, continues throughout the building's effective life sustaining intended functions. A critical examination of a building process reveals two essential streams of resource flow as shown in Fig. 2.

Intake resources flow into the building as input to the building ecosystem while *Outcome* is resources that flow out of the building to the ecosystem (Kim and Rigdon, 2000). Strategies of protection of resources are multi thronged as given below.

(1) Energy conservation:

It is achieved through the overall built form design, incorporating the principles of energy efficient design in orientation, organization of spaces, form of building, materials of construction particularly glazing, improved technology and intelligent building systems. The motto '*energy conserved is energy generated*' is worth adopting. Further, the design of the built form shall consider integration of energy generation by way of photovoltaic panels, small wind turbines etc. Energy reduction may be achieved by the use of atriums, double roof, shorter span, external shading, terrace and vertical landscapes or even by the use of trombe walls. These consists of a vertical wall, built of a material such as stone or concrete with glazing on its outside. Sunlight incident on the glazing generates heat which is conducted through the wall also, warms up the air between the glazing and the Trombe wall surface. This warm air may be channeled for use depending on the heating needs of the built form. It is important to comply with the GRIHA or other effective sustainability codes in force in the country.

(2) Water conservation:

Any building requires large quantities of water for various purposes that range from domestic uses to irrigation. Water requires treatments at various levels for specific uses. These treatments along with its transportation and delivery consume energy. Conservation of water is of increasing importance in these days of climate change and scarcity of water. It is the basic responsibility of every designer to address this issue seriously. Strategies for conservation of water may be made by the use of intelligent and improved water supply and sanitation systems, introduction of intelligent water management and control, change of life habits, and the use of intelligent design and detailing. Water recycling is important and every built form design shall include water recycling system in order to reduce consumption of treated water. Equally important is water harvesting from roof top and paved areas for the use for supplemental requirements. Every attempt shall be made to harness and treat roof water and its useful storage. Replenishing the underground water sources is vital to sustainability. Every attempt shall be made to increase percolation of rain water to the site soil. Landscaping schemes shall address this issue successfully by the

Fig. 2 The input and output streams of resource flow.

integration of roof gardens, perforated pavements or even by the appropriate use of rain pits. Personal use of water is the responsibility of every citizen and shall be practiced on a daily basis to limit and reduce waste water.

(3) *Material conservation:*

Material conservation focuses on every particular resource necessity for building construction and operation. Procurement, production and transportation of materials consume energy which is embodied in these. Major influx of building materials occurs during the construction stage. The waste generated by the construction and installation process is significant. Flow of materials continues even after construction that is used for maintenance, replacement and renovation. Consumer goods flow into the building to support human activities. All of the construction materials, in the end, *are outcome raw materials or waste*, either to be recycled or dumped in a landfill (Federle, 1993). Responsible design is the outcome of a thoughtful attitude to waste reduction at all stages of built form design and use.

Environmental impacts of energy consumption by buildings occur primarily away from the building site, through mining or harvesting energy sources and generating power. The energy consumed by a building in the process of heating, cooling, lighting and equipment operation cannot be recovered and these gets added up. Strategies for material conservation include intelligent form design, stringent area and space requirement calculations, effective management and use of technology in the performance of intended functions. Further, every attempt shall be made to avoid wastefulness through efficient planning and detailing. It is worthwhile considering appropriate legislation for levying tax; *luxury or green*, on buildings that exceeds the material and energy limits prescribed.

Life Cycle Design (LCD)

As it is seen in Fig. 3, the life cycle process of the building is a linear process consisting of three major stages (Curran, 1996). Each of these stages calls for sustainable approaches and strategies in an effort to achieve the goals envisioned.

Life cycle design (LCD) is not prescriptive, but suggestive in nature. However, LCD can contribute information and facilitate the effective decision making process. This approach accounts for the environmental consequences during the entire life cycle of construction materials; *from procurement to return to nature* (Burall, 1996). Life cycle of a building can be brought into three phases namely *Pre-building, Building, and Post-building*. The phases can be developed into LCD means that focus on minimizing the environmental impact of a building. Analysis of the building processes in each of these three phases throws light to the dynamics of design of the built form, its construction, operation, and effects of disposal from it to the ecosystem. Pre-building phase includes site selection, building design, and building material processes. However, this phase does not include the construction or installation of the building. Sustainable design approach considers meticulously the environmental consequences of construction materials, design of the structure, its orientation and impact on the landscape (Dimson, 1996). The procurement of building materials impacts the environment in various ways; *unscrupulous felling of trees leads to deforestation, mining mineral resources disturbs the nature and creates environmental pollution or the like*. Building phase refers to the stage in the life cycle of a building when it is physically constructed and operated. In the sustainable design, the construction and operation processes shall embrace means to reduce environmental impact, resource consumption and sick-building syndrome. Post-building phase refers to the stage which begins when the useful life of a building has ended and its building materials are turned in to resources for other buildings or waste to be recycled or returned to nature. The strategy is to reduce construction waste by recycling and reusing buildings and building materials.

Livable Design – (LD)

Livable Design refers to the livability of all constituent spaces in built forms and spaces that form various groups in the global ecosystem (Celebi and Aydýn, 2001). The livable design is concerned about the healthy coexistence among buildings, their environment and their respective occupants. Its broad objectives are intended to preserve the elements of the ecosystems in an effort to facilitate human survival. Built forms are intended to provide safe and healthy environments that are comfortable for their occupants which in turn enhance their satisfaction and productivity. Livable design objectives, therefore, could be evaluated under *Generation and sustenance of natural conditions, Creation of satisfactory urban design and site, Generation of human comfort* (Table 1).

Fig. 3 The life cycle process of building.

Table 1 Conceptual framework of sustainable design

Objective	Protection of resources – PR	Lifecycle designs – LCD	Livable designs – LD
Strategy	Energy, Water and Material Conservation	Pre-building, Building Post-building phases	Generation and sustenance natural conditions Creation of satisfactory urban design and site Generation of human comfort
Achievement	Optimized space and systems, Materials Conserved	Total approach to Built form design, Lower energy consumption, waste generation	Acceptable and healthy exteriors and interiors, Improved performance and health of users

It is important to minimize the impact of a built form on its local ecosystem. The totality of neighborhoods, cities and entire geographic regions can reap the positive benefit from harmonious and complimentary planning on all fronts of resource, energy and pollution. Such a coordinated effort leads to an appropriate urban environment accommodating the specific needs of its context. Needless to state that sustainable design shall offer human comfort; both internal and external, in the interest of individuals and the nation at large.

Strategies for Creating Sustainable Architecture

The prime intension of strategies of sustainable architecture is to generate beneficial solutions in terms of quantity and quality which lead to physical and psychological comfort. The three objectives of sustainable architecture; *Protection of Resources*, *Life Cycle Designs* and *Livable Designs*, gives a comprehensive understanding of the environmental issues related to architecture.

Protection of Resources – PR

Resource demands of a built form are directly related to its utilization efficiency of resources. Concern for conservation of energy, water and building materials would yield specific design methods that would reduce the need for nonrenewable resources in built forms. Built form *outcome* management reduces its effect on environmental by lowering the level of waste generation and appropriate waste management (Thormark, 2001) (Fig. 4).

Energy conservation

Energy consumption by built forms accounts for a major share of energy requirement of any country. Therefore, one of the main objectives is to reduce energy requirement and consumption of fossil fuels used in the generation of energy. Operational phase of buildings consume energy for heating, ventilation and air-conditioning, lighting and transportation. Strategies to be adopted to achieve energy conservation shall be holistic and include energy conscious urban planning with emphasis on eco-cities with its neighborhoods and built forms that are sustainable and planned for public transportation, pedestrian walkways and walk-up work places. Favour mixed use for such cities with zoning laws facilitating balanced developments and walk-up work places. Ensure balanced development of rural areas and avoid migration and urban sprawl by encouraging redevelopment of existing sites and adaptive reuse. Do not encourage unscrupulous development and heavy generators of traffic without efficient integration with public transport networks (Table 2 and Figs. 5 and 6).

Materials conservation

Sustainable designs get realized in terms of building materials, components and products, the choice of which poses a tremendous task which requires understanding of materials and standards of performance. Cost and availability are likely dominant factors in normal building projects. It is also important to have the general awareness regarding the diverse implications of production, consumption and recycling on the environment. Therefore, adopt a lowered consumption which in turn reduces the need for production and generation of waste (Table 3 and Fig. 7).

Fig. 4 Grid and glass form for cultural sustainability in built form. Gable implies the presence of atrium and the influence of traditional Kerala architecture. *Architect: Dr. Abraham George.*

Table 2 Strategies for sustainable design – PR

Strategy	Description – Energy conservation
Energy conservation Energy-conscious site planning	It optimizes the use of natural resources on the site. Southern exposure for passive solar heating, use of trees for shade in summer and solar heat gain in winter. Planting of evergreens on the north of a building for protection from winter winds and improved energy efficiency. Use of water in various forms to provide natural cooling and humidification. Use of passive heating and cooling through the use of trombe walls, atriums for heat, light, and ultraviolet radiation necessary for photosynthesis of indoor planting. Passive solar architecture offers design schemes to control the flow of solar radiation using building structure through the use of intelligent shading devices, active and passive solar heating systems, and use of photo voltaic panels.
Glazing, cladding and insulation	Use of high-performance glazing and wall insulation in cladding to prevent both heat gain and loss. Reduction of heat transfer reduces the building's heating and cooling loads and energy requirement. Compounded benefits of smaller systems are many; smaller HVAC equipments needs lower initial investment, generates lesser mechanical noise and increases sonic quality of indoors and system reliability.
Day lighting and ventilation	Proper orientation of built form, organization of spaces and intelligent fenestration design maximizes the use of natural light in an effort to conserving electrical energy, reduces peak electric loads and cooling needs. Moreover, day lighting enhances the illumination quality of indoors, increases physical and psychological well-being and productivity. The qualitative benefits of day lighting are far more significant than its energy-savings potential.
Energy-efficient equipment	Operation and maintenance of equipments are the longest activities whose costs exceed construction costs over a building's lifetime. Scrupulous selection of high-efficiency lighting, heating, cooling, and ventilation systems is critical. Consideration to energy saving is to be given over initial costs.
Embodied energy building materials	Use materials with low embodied energy; <i>how much energy is needed for production</i> . The embodied energy of a material attempts to measure the energy that goes into the entire life cycle of building material. Use local materials, over transported materials to save transportation energy and reduce pollution (Burali, 1996).
Water conservation	Holistic view on water conservation is essential with all efforts for achieving self sufficiency namely; <i>reduction in requirement, reuse and recycling, water harvesting and practice of water management</i> . Adopt recycling of both grey water and sewage. Though grey water is not of drinking-water quality, it does not require intense treatment as equivalent to sewage therefore, can be recycled within a building, to be used for irrigation or for sanitary purposes. Efficient water supply systems and fixtures can reduce consumption of water and generation waste water. Vacuum-assisted and biocomposting toilets and water-less urinals reduce water consumption. Biocomposting toilets treat sewage on site, eliminating the need for energy-intensive municipal treatment. Encourage the use of indigenous and discriminatory landscaping for reducing water consumption.
Alternative energy sources	Incorporate solar, wind, water, and geothermal energy systems to reduce or eliminate the need for external energy sources. Use of low speed wind turbines could prove to be beneficial if, the built form design is done aerodynamically to channel and generate wind speed to generators.

Lowered consumption in building α Lowered production of waste and Need for production
Optimization of space requirement α Material Requirement, and Lowered operational costs

Life Cycle Design – LCD

The objectives of Life Cycle Design with its three stages; *pre-building, building, and post-building*, calls for the design strategies designed to achieve sustainability in the design of built forms (Table 4).

Fig. 5 Atrium-lit central courtyard of Chemical Engineering Block, NIT Calicut. *Architect:* Dr. Abraham George.

Fig. 6 Atrium-lit central courtyard of Students' Center, NIT Calicut. *Architect:* Dr. Abraham George.

Table 3 Strategies for sustainable design-material conservation

Strategy	Description – Materials conservation
Building material conservation	Attempt to optimize space requirement and estimate scrupulously the built-up area need. Attempt additional discussions with clients, even at the cost of inconvenience on the part of architect. Floor to floor heights multiplies the material requirement which often goes unnoticed. Determine floor to floor height meticulously with proper detailing and efficient system design and intelligent ceiling designs. Avoid excess trimming of materials to fit non-modular spaces that generates more waste.
Direct material reduction	
Reuse of built form	Accommodating existing buildings that are designed for specific functions to new uses, is one of the most effective methods of material conservation. Larger free spans, <i>within the prescribed reach of day lighting</i> , enhances the adaptability of built form. Combining the reclaimed or recycled materials obtained from demolished buildings in new is another method of material conservation (Kua and Lee, 2002). Many construction materials, such as wood, steel, and glass, could be easily recycled into new materials. Proper documentation of carefully dismantled joinery would facilitate its direct reuse in new buildings, particularly those built intentionally to generate heritage images. These attempts preserve embodied energy.
Consumer goods in buildings	Consumer goods lose their original usefulness in time and amounts to waste; <i>goods that have lost their original usefulness</i> . The useful life quantifies the time of conversion of goods from the usefulness to waste. It needs careful consideration in recycling short-life consumer goods since shorter the useful life of consumer goods, greater the volume of useless goods. As a rule of thumb, avoid the recycling of shorter life building materials.

Table 4 Strategies for sustainable design

Strategy	Description – LCD
Life cycle design:	Design and detailing are extremely important which are to be combined with building materials to express architectural forms.
Pre-building	Material production and related processes can produce global-level impact that can have long-term consequences. Therefore, architectural designs together with the building materials chosen are examined for their environmental impact at the Pre-Building Phase. All efforts shall be made to avoid wasteful expressions using high-embodied energy materials. Instead, care shall be exercised to use reusable materials intelligently and efficiently integrated with architectural design.
Building materials	Prefer to use sustainable materials made from renewable resources since renewable resources could be replenished at a faster rate exceeding that of consumption. Materials produced from nonrenewable materials like petroleum, metals or the like ultimately amount to no sustainability even if current supply seems adequate. Argument favouring the use of steel and glass based on their implied potential for reuse shall be favoured with careful detailing and effective specifications. It is important for designers to have knowledge of the harvesting of raw materials and the material processes in order to make right selections to ensure sustainability. Adopt materials produced without causing ecological damage which are locally available and cause least negative environmental impact. Though mud is a traditional building material which appears to be sustainable, a careful examination would prove it, not, since the same mud is good for sustenance of flora and retention of essential topographical feature. Adopt the use of recycled materials to reduce waste and save scarce landfill space. Moreover, recycled materials preserve embodied energy of their original form and reduce consumption of raw materials. Many building materials like steel are easily recyclable thereby eliminating the need for more mining and milling operations. Further, use durable materials with longer life and less maintenance, in order to limit the exposure to irritant cleaning chemicals.
Building phase	Strategies to be adopted for achieving sustainability in the Building Phase address the impact of construction and operation processes on environment.
Building materials	Avoid felling of trees by meticulous designing, integrating trees into the built form. Plant additional trees in order to account for damages and depletion of flora. Choose to minimize ecosystem damage on the site by careful planning and minimizing the use of heavy equipment. Topographical modifications and site excavations should not alter or block the flow of prevailing surface and groundwater flows. Use nontoxic materials to ensure health of occupants of built form since they spend more than three-quarters of their life indoors. Adhesives used in interior works produce toxic emissions for prolonged time, even after construction is over. Use only nontoxic cleansers since toxic airborne cleaners tend to remain in the ventilation system for extended periods.
Post-building phase	Examination of the environmental consequence of structures that has outlived their useful life is done, in order to decide on the future course of action; <i>reuse, recycling or disposal</i> .
Building materials	Resort to direct reuse or recycle in order to allow an existing building to become a resource for new one, since disposal requires incineration or landfill dumping, that adds up to the overburden of environment (Ngowi, 2001). Reuse of building as it is important, since the embodied energy which includes the sum of energy embodied in the materials and that went into its construction is considerable. Adaptive re-use is another viable option for energy conservation. When both these approaches fail, try reuse of building components. Discourage the inconsiderate suburbia in favour of reuse of existing built forms and infrastructure since, developing new suburbs from virgin woods or fertile fields destroys the agricultural land and dislocates the rural population which might result in tension and unrest as witnessed in <i>Singur</i> in West Bengal.

Table 5 Strategies for sustainable design – LD

Strategy	Description – LD
Livable design	Retain existing topographical contours by sympathetic design with a view to enhance microclimate. Moreover, unscrupulous alteration of contours will adversely affect existing water courses microclimatic and microclimatic wind movement. Prefer not to disturb site water table by avoiding excavation below water table since large obstructions like buildings, into the water table will disturb the natural flow. Avoid exposing water table during construction since it will increase chances for contamination.
Preservation of natural conditions	Do not spoil the existing flora and fauna, but preserve these vital elements of the site and environment. Native plants and animals; <i>if treated as resources to be conserved rather than as an obstacle to overcome</i> , will compliment the completed built form and make it a more enjoyable space.
Urban design and site	Urban design and planning strategies brings in sustainability at a larger scale, in the totality. It is important for the balanced geographic positioning and distribution of green zones considering the specific nature of the context and the special aspects of the nation to which it is applied. Avoid indiscriminate concentration in urban areas, especially in the Indian context, but encourage sustained growth of both rural and urban areas. Adopt to integrate design with public transportation, especially walk-up work places, or nodes, since sustainable architecture on an urban scale must be supported with efficient public transport networks. Avoidance of public transport results in the use of individual transport means which create problems of pollution, smog, traffic bottlenecks and parking. Encourage mixed use development including residential, commercial, office, retail and institutional spaces. It reduces the use of vehicles, encourages community feeling, dynamism and security with reduced tendency for vandalism.
Design for human comfort	Potential subjects of environmental impact in regard to human health include labourers; <i>both skilled and unskilled</i> , building users and the community in general (Osso <i>et al.</i> , 1996). It is important to provide comfort in terms of thermal, visual, and acoustic environments in order to enhance the performance output of users. Insist on the use of nontoxic materials with low or no VOC emissions to reduce health hazards and avoid sick building syndrome. Studies have established the importance of visual connections to exteriors; <i>the biological clock synchronized with the periodic cycle of day and night, which gets connected to the ever-changing dynamic natural exteriors by way of open or glazed atriums open vertical zones in built form</i> , that link the interiors with exteriors, in an effort to boost the performance and wellbeing of occupants. Similarly integration of operable windows is essential for the occupants to have proper management of openings in an effort to have passive energy efficiency by periodical opening or closing as per favorable outdoor conditions (Abraham, 1997).
Social responsibility	Honour <i>Equal Opportunity Act</i> and design for accessibility by the physically challenged for all spaces in the built form. Once the built form is designed for the physically challenged; <i>wheel chair bound, people with crutches, visually challenged, hearing deficient, children, pregnant and people with ailments</i> , its usefulness life and sustainability gets enhanced.

Livable Design – (LD)

Objectives enshrined at the three levels; *ecology, urban design, and human comfort*, and the social responsibility of sustainable architecture are achieved through the following specific strategies (Table 5).

Need for Alternative Concepts

It is important to understand the limitation of traditional design models to generate unique built forms that meet the requirements of sustainable designs. Mostly, the inherent inability in the traditional models is manifest by way of stereotyped thinking which leads to no atypical designs. It is worthwhile to ponder the words of Albert Einstein “*We cannot solve the problems by the same thinking that created them*”. Due to the lack of novelty in conceptualization and approach, such designs offer very little scope for optimization, lowering energy and resource consumption. This problem of stereotype could be resolved creatively by a search for alternate models in designs. Nature, at this juncture, presents itself with harmonious designs that are sustainable, self-supporting and self organizing. Solutions that are found in the harmonious natural systems are always in evolution, perfecting and adapting to their contexts. Thus, what is seen today has been working over billions of years for evolving a reliable and sustainable model. Adoption of these evolved models in human designs would facilitate the making of future systems better sustainable; environmentally, ecologically and economically. Hence, Biomimicing reveals itself as a fine model to follow in the generation of alternative sustainable design solutions.

Biomimicry

Biomimicry is a new science that studies nature’s best ideas and principles and imitates these designs and processes to solve human problems. In other words Biomimicry leads to *innovations inspired by nature* (Biomimicry Institute). Though some of nature’s basic

configurations and designs can be copied, most ideas from nature are best adapted when they serve as *inspiration for human-made designs and productions* (Bar-Cohen, 2006). Adaptation of natural systems and organisms has facilitated better understanding of related phenomena and principles in the design of novel designs, devices with better features and capability. For example, the cell-based structure that is the building block of biological systems has the ability to grow with fault-tolerance and self-repair. With the adaptation of Biomimic structures based on nano-technologies, such designs and devices are possible in human-made designs, but not with traditional materials and processes. On a different level, there exists the evident, inspirational link between the design of tongs and bird's beaks. The same inspiration is evident in the foldable hand-held fan design and the peacock feather display; *a magnificent attempt to impress the female*. Further, there are organisms like spider that feeds on its own saliva; which otherwise would be a waste, nurturing itself.

One of the important features of nature is its evolution by responding to the system needs and generating solutions that work. Nature remains in an open, dynamic system establishing balance and continuous refinement in all its productions. Each of the successful natural creation that passes to the following generation has to withstand the test of survival, establishing the 'best fit' for the following generation. Nature's laboratory through evolution generates information that is coded in genes and transferred to the following generation through the process of self replication. Nature thus, is perfecting models worth copying and inspiring novel engineering methods, processes, materials, algorithms, and designs. In a similar way production of designs and the elements and their organization in the design produced shall remain in a continuum of evolutionary changes, permitting adaptation and attainment of the 'best fit'. Mimicking of nature may be done at various levels beginning with the full and complete appearance of the natural system to its every system detail in part or full. On the other extreme, natural models are interpreted and transformed in the making of human-made designs. Such mimicking of life-systems demands the full capacity and intelligence of humans.

Principle of 3Ms

Model

Accept nature as the standard and imitate its system designs, processes and strategies at any level as deem fit, to live sustainably. Investigations of such natural systems reveal the details of system composition and their organization at the general level and the details of elements, processes and strategies at the specific level. Biomimic designer has the freedom of choice to operate at the level of optimum advantage, in tune with the technological capabilities and resources available.

Mentor

Nature is the finest teacher and mentor for the designers of all the times. Genius designers like Leonardo da Vinci, mathematician Leonardo Fibonacci to architect F. L. Wright have looked to nature for inspiration, ordering and performance of their productions (Knott *et al.*, 1997). Learning from the vast 3.85 billion years of research experience gained through the nature's lab and evolutionary process would immensely benefit the future designers (Lowman, 2002). One has to be, therefore, intelligent enough to understand, interpret and adopt the nature's time-tested, creative and sustainable solutions and ordered processes for sustainability individual built forms or in collective urban forms.

Measure

Biomimic designers view nature as an ecological and sustainable standard and accept what it does. Nature with its organisms maintains sustainability and survival through constant adaptation and satisfying of just needs without causing congestion and contamination. Unlike organisms, humans plunder the nature for pleasure and satisfy their greed, causing imbalance and violent repercussions at times. Human adaptations rarely follow biological laws; instead, *attempt to change the very constraints that force their own adaptation*. Hence, the antithesis of biological laws is prescribed in the industrial, financial and civil systems. It is worthwhile to recall the statement of Mahatma Gandhi *"The nature has enough to satisfy our need but not greed"*. It is therefore, imperative for a Biomimic designer to comply with nature's standards in the maintenance of sustainability and adapt to the forces of natural transformation rather than aggressive living.

Goal

Biomimic designs imitate life systems that learn, grow and adapt incorporating continuous feedback, inheriting innovation and refinement for effecting evolution and the best fit. This might offer the possibility of a self evolving system having the capability of production, growth and consumption of waste. In this process the problem of waste would be converted to generation of raw materials!

Seven Point Strategy

Optimize rather than maximize

Natural systems are programmed to optimize, never maximize their system output. Every natural system and corresponding elements are designed to be *multifunctional in design* thus enhancing versatility of design and avoid multiplying need for specifics.

A visible example is human hand. Versatility further, reduces consumption of resources and inconveniences. Further natural systems exhibits extreme '*form to function*' fit.

Act independently

Natural systems are self reliant with no need for dependence at all levels of production consumption and disposal. Natural system is equipped for recycling all materials on expiry of useful life and turns *waste to food*. On the contrary, waste production is inherent to all human productions chocking every disposal system. Adopting the natural position of '*waste to useful stuff*' would inspire Biomimic designers to generate individual or collective built forms that would facilitate useful spaces that are *re-transformable* and avoid the need for fresh raw materials, other resources and energy. A Biomimic design shall therefore, *enable independent performance, foster cooperative relationships and facilitate retransformation*. Often built forms meets with the need for self organizing and remain in balance. A simple example is a corporate building designed for a specific set of functions faces the need to get transformed to house altogether different set of functions and users due to changes in economy or other formative forces in order to stay fit. If a built form is designed to be rigid without any scope for readjustment in an effort to be transformed in self organization, it leads to unfit and extinction. Cases of demolition of high-rise apartment buildings that fail to generate acceptable living conditions within and exterior environments endorse the necessity for self organization and retransformation when situations call for it in an effort to maintain balance and harmony (Jacobs, 1961; Newman, 1973).

Manufactures own needs

Traditional models do consume but never produce for the needs it has; be it energy or any other resource. Whereas, through Biomimic designs many if not all of the needs of a built form may be generated fully or partially. Power for example, to be generated by alternate means by creatively using wind, sun or even geothermal, multiple use, involvement of human and animal power or the like in an effort to meet the built form needs. A built form in isolation could be used to tap the wind energy by way of its aerodynamic design and integrated wind turbines. Similarly, built forms could be designed meticulously to tap solar energy; both passive and active, through passive and appropriate courtyard designs or photovoltaic integrated designs. Developments in material science and photovoltaic designs present the designers with transparent thin film options amounting to sustainable and creative built forms. At city level collective built forms of cities could be creatively composed to generate self shading, light and ventilation within and around with appropriate reradiation specified, in an effort to counter the increased energy demand resulting from heat island formation and ill-lit designs.

Imbibing the lesson of consuming what is made by own, locally not brought from elsewhere, Biomimic designers have to begin with the use of locally available and self generated resources, rather than using those brought from afar, at higher cost and energy consumption. Preferring to be in harmony with nature and the context of design would immensely benefit Biomimic designs.

Resourceful and opportunistic

Biomimic designs shall derive its uniqueness and strength from shape rather than the material, and building from the bottom-up. While using simple and common building blocks, creatively explore the possibilities inherent in forms rather than simply bogged-down with materiality and available technology. It simply means choosing the 3D form advantage over 2D traditional models, beginning with the preference for frames over post and lintel. Biomimic designs shall prove to be resourceful and creative naturally in diminishing consumption and enhancing self generation, even by reducing need exercising preference to intelligent built forms.

Cyclical processes over linear

Traditional models of designs are inherently linear and additive in nature. Linear additive models have proved to be ineffective with larger consumption and wastage of resources at all stages of built forms, beginning with erection through operation and maintenance, leaving behind wastage and byproducts. On the contrary, cyclic processes tend to be inherently effective and efficient at all levels proving to be naturally sustainable as in the example of falling leaves turned in to fertilizers for the tree through biological involvement.

In the evolutionary Biomimic designing feedback loops are inevitable. These loops are to be effectively incorporated in the continuous refinement of the process resulting in better designs. In doing so the natural cycles; *Carbon cycle, Water cycle and Seasons*, are to be honoured for maintaining sustainability.

Durable and tough

Biomimic designs are to be as durable and tough in tune with the diverse natural law to be '*operating at low-risk*' as in the preference for a forest against a single agricultural crop. In such a rugged system each of its components systems shall be complimenting one another.

Decentralized and distributed

Nature operates at surplus mode having back-up maintained operational and maintains itself even in the failure of a component system. Multi-supported design increases the operational reliability and earns credibility.

Biomimic Thought Process

- *Identify the real challenge*
 - What do you want to “do” (not make)? Be open, rational and creative. Learn inquisitiveness from kitten!
- *Interpret*
 - Identify the functions / purpose
 - How nature does perform function?
- *Discover Nature’s Genius*
 - Go for a walk outside and observe and brainstorm. Look for the precious stones!
- *Abstract*
 - What patterns and principles work for your problem? Be creative and prudent.
- *Emulate or Imitate*
 - Play and design
 - Brainstorm and converse
- *Evaluate*
 - Revaluate and Re-Imagine the design deeper and rigorous each time with holistic thinking in order to solve the entire problem. It might be necessary to redefine to solve the problem as a whole, not in parts.

Formula for Sustainable Future That Offer Waste Reduction

Intellectual Capital + Nature’s Genius = Innovative, Sustainable solutions

If we are limited, it is by our own dreams! Therefore, dream great and be a B₂, *Beautiful Biomimic*.

Conclusion

Concepts and strategies aim to generate sustainable architecture which is the need of the hour and vital to the existence of life forms on earth. In this process, waste reduction or no waste production shall be attained through adopting alternative concepts to rescue a world that is already choked. There exists confusion from multiple mushrooming agencies and competing visions trying to define and establish what ecologically sustainable architecture is, especially of its scope, application and end result. The scientific and technical complexity involved along with the commercial and political interests amalgamated to its objectives make ‘defining sustainable architecture’ a delicate issue. These approaches lack a real concern for the unique survival and special needs of the context to which such prescriptions are applied. Further, it is important to understand the limitation of traditional design models and look for better alternatives including Biomimicry.

Sustainable architecture can be achieved primarily by reducing the consumption of materials, energy requirement involved both directly and indirectly and the generation pollution. Space and area optimization warrant an effective strategy in the achievement of reduction of the need which lowers the generation of pollution. Architects have a greater role to play, therefore, at this important issue. Engineers have an equally important role in the design and selection of optimized systems; *mechanical, electrical, transport and disposal*, which are vital for the efficient performance of the built forms.

It is important to consider necessary legislation to impose ‘green tax’ on buildings that exceed the limits of material and waste generation; to be stipulated for unit area of foot print on site. Further, those designs that comply with the norms shall be encouraged through incentives. Architectural schools shall promote creative designs instead of stereotypes.

Additional thrust is to be exercised in regard to the generation of environmental awareness, waste reduction and the design detailing and practice for sustainability in order to achieve this vital responsibility we owe to the posterity and ourselves. Education in architecture and allied fields shall impart rigor and soundness to design professionals engaged in the design, production, operation and reuse of built forms (Celebi and Aydýn, 2001). It is also important to accept the relationships and interconnectedness within the ecosystem and the built forms that designers develop. It is the vital responsibility of architects to find creative design solutions that facilitate well-being and harmonious coexistence of organic and inorganic groups (Yeang, 1995). A conceptual layout and an array of feasible strategies are elucidated for appropriation as any project demands. It is important to view these strategies as a positive response to the awareness of the finiteness of the limits of ecosystem.

There is inherent inability in the traditional models and stereotyped thinking leads to atypical designs. The problem of stereotype could be resolved creatively by alternate models wherein mimicking natural systems holds great potential. Natural systems are always in evolution, perfecting and adapting to their contexts over billions of years. Adopting the natural models through Biomimicing facilitates the making of future systems better sustainable. The principle of 3M and the Seven-point strategy is elucidated in generating Biomimic designs. Further, the Biomimic thought process is illustrated in evolving a formula for sustainable future.

It is right time that the Government sets-up a *Project Sustainability Authority* for both public and private sector projects in the wake of the numerous agencies mushrooming with the sustainability and green agendas with no eye for the real needs and special

nature of developing nations like India. Premier research and educational institutions could be made a vital part of the 'Authority' wherein the Nation can expect fairness without outweighed importance assigned to the concerns of corporate sector, forgetting the balanced development of rural sections of the country.

Nomenclature

I_{μ}	Annual mean solar radiation	T_{hot}	Temperature of the hottest month
PMV	Predicted Mean Vote	T_{in}	Indoor dry-bulb temperature
RH_{μ}	Annual mean relative humidity	T_{in}	Indoor dry-bulb temperature (instantaneous)
$T_{A\mu}$	Annual mean outdoor dry-bulb temperature	T_{mmax}	Monthly maximum outdoor dry-bulb temperature
T_{amax}	Annual maximum outdoor dry-bulb temperature	T_{mmin}	Monthly minimum outdoor dry-bulb temperature
T_{amin}	Annual minimum outdoor dry-bulb temperature	T_n	Neutral temperature
T_{cold}	Temperature of the coldest month	T_{out}	Outdoor dry-bulb temperature (instantaneous)
T_{comf}	Comfort temperature	T_{rm}	Running mean temperature
		TSV	Thermal sensation vote (subjective)

Introduction

According to ASHRAE Standard 55 (ANSI/ASHRAE, 2004) thermal comfort is defined as “the condition of mind which expresses satisfaction with the thermal environment”. The perception of thermal comfort varies from person to person due to physiological and psychosomatic differences in people. Primarily, thermal comfort is affected by climatic factors such as temperature, air speed, humidity, and radiant temperature; human factors of level of activity and behavioral factor of clothing insulation (Fanger, 1973). Building enclosure acts as a medium, which moderates the outdoor weather changes and facilitates comfortable indoor climate. As a corollary, we infer that the role of the enclosure is crucial when the outdoor thermal boundary conditions are severe. Cold climate zones characterized by low temperatures for the majority of the year are typically prevalent in high latitudes regions or higher altitudes of middle and low latitudes. The role of enclosure is hence a critical factor in ensuring comfortable living conditions indoors. Buildings in cold climates are required to minimize heat loss through the envelope. Traditional buildings in cold regions incorporate passive solar heat gain strategies such as high thermal mass of walls and roofs (Stevens *et al.*, 2016). Apart from physiological heat balance, thermal comfort, by definition, is associated with the “condition of mind”. According to adaptive comfort principle, if a change occurs to produce discomfort, people react in ways which tends to restore their comfort (Nicol and Humphreys, 2002). This change can be physiological, psychological and behavioral adaptation. In countries such as India, centralized heating systems are not an integral part of majority of the housing stock. Comfort conditioning is primarily through conventional and localized heating systems. Design of buildings, enclosure and thermal adaptation are hence crucial for sustainable living conditions in such building types.

The chapter sets to (a) present a characterization of cold climate in India; (b) discuss sustainable design practices and compare the existing housing typologies in cold climate; and (c) discuss thermal adaptation in cold climate of India and its implication on building thermal design. The study focusses on cold climate of North India and specific examples of Himalayan hill settlements is presented. The study employs geo-spatial analysis of thermal conditions using the data from worldclim (2016) and CRU CL v. 2.0 (a high-resolution data set of surface climate over global land areas) (New *et al.*, 2002). Section “Cold Climate of India” of the chapter presents a statistical characterization of cold climate based on the thermal severity variations. Thermal comfort assessment of four representative locations is presented. Section “Thermal Adaptation in Cold Climate” discusses the thermal comfort and adaptation in this region. Thermal adaptation analyzed through longitudinal and transverse surveys conducted in these four locations during summer and winter is discussed. Neutral temperature isotherm generated for the study region is presented. Section “Buildings in Cold Climate” describes the building design requirements and presents a bio-climatic classification of the cold climate zone based on Mahoney’s method. Thermal performance of the existing housing measured through real-time field studies are discussed. The study highlights the role of climate responsive design in order to achieve sustainability.

Cold Climate of India

Definitions of cold temperature vary across different climate classification methods. According to the modified Köppen climate classification by Peel *et al.* (2007) cold climates are those having $T_{hot} > 10^{\circ}\text{C}$, and $T_{cold} < 0^{\circ}\text{C}$. Fig. 1 presents the Köppen Geiger climate zones of the Indian cold regions. Large swathes of Himalayas are classified under very cold (EF, ET) conditions while others have milder (Dfa, Dfb, Dfc, Dsb, Dsc, Dwb, and Dwc) environments.

According to the National Building Code of India (NBC), the cold climate zone is a region that has a mean monthly maximum temperature less than 25°C for more than six months (Bureau of Indian Standards, 2016). By this definition the entire Himalayan region is encompassed in a single cold climate zone.

Fig. 1 Köppen-Geiger classification of the study region.

Sub-Classification of Indian Cold Climate

A sub-classification of the Indian cold climate is required to address the variations of temperature, humidity, and solar radiation. Using a high-resolution (30'') spatial dataset of temperature from worldclim and 10' resolution data from CRU (Fick and Hijmans, 2017; New *et al.*, 2002), the NBC's cold climate is re-created in detail. Fig. 2 presents the distribution of annual maximum (T_{amax}) and minimum temperature (T_{amin}) and mean solar radiation (I_{μ}).

The range of annual mean temperature spans from 23°C to as low as -34°C. The extreme temperature ranges from 25°C to -42°C. Similarly, a wide variation is observed in solar radiation availability as shown in Fig. 2. These intra-climate zone variations highlight the need for a climate zone sub-classification. This will facilitate effective regulatory control over thermal performance and energy use of buildings in this region. A rational sub-classification is discussed further.

Three variables (a) annual mean temperature (T_{au}), (b) annual mean relative humidity (RH_{μ}), and (c) annual mean solar radiation (I_{μ}) are used in the sub-classification. The 30'' spatial resolution data points of the above variables in cold climate zone are statistically classified. T_{au} values are classified into three groups (cutoffs at the 20th percentile and 80th percentile). Relative humidity (RH_{μ}) and I_{μ} are classified into two groups (cutoff at the 50th percentile value). The T_{au} , RH_{μ} and I_{μ} groups are spatially overlaid to obtain 11 subgroups referred as CZ(n). Table 1 shows the details of 11 sub-groups characterized by high, medium or low temperatures and high or low relative humidity and solar radiation.

Root Mean Square Error (RMSE) associated with the maximum temperature, minimum temperature, and average temperature are 1.39°C, 1.29°C, and 1.12°C respectively. However, the actual errors differ depending on the "complexity of the terrain" and the "density" of the weather stations. Absolute RMSE for solar radiation is slightly higher at 1.45 MJ/m² (Fick and Hijmans, 2017). Estimated relative humidity has errors up to ±15% (New *et al.*, 1999). Fig. 3 presents the spatial map of the sub-classified cold climate zone.

The north and north-east peripheral regions fall under CZ1 which experience low T_{au} , RH_{μ} and I_{μ} . The southern fringes fall under CZ11 which experience T_{au} , RH_{μ} and I_{μ} . CZ11 further merges with the composite climate zone of the National Building Code. The relevance of the sub-climate zones is validated using the ground station data obtained from the Indian Meteorological Department. The thermal severities, heating and cooling degree hours, relative humidity and solar radiation variables showed a statistically significant difference. The above method of classification provides a simple, reliable and precise estimate of intra climate zone thermal severities. This enables regionalization of the thermal performance regulations of the major climate zone provided by national and international codes. For instance, the sub climate zones can be regionalized to district administrative boundaries in order to facilitate effective implementation of building thermal regulation and energy efficiency codes.

Total				378,953.8

Climatic Analysis for Representative Locations

From the above sub-classification (**Fig. 3**) four geographical locations are selected on the basis of climatic severity. The locations Keylong (32.58°N 77.03°E), Manali (32.27°N 77.17°E), Naggar (32.12°N 77.17°E) and Kullu (31°56'42"N 77°6'56"E) represent CZ5, CZ5, CZ9 and CZ11 respectively. A statistical clustering of the daily mean temperature, humidity ratio and solar radiation is performed for the four locations. The two step clustering yielded four clusters. **Table 2** presents the details of the clusters and the cluster mean values of temperature, humidity ratio and solar radiation. As shown in **Table 2**, Keylong (CZ5) experiences sub-zero

Fig. 3 Sub-zones in the cold climate of India. (CZ=Cold Zone).

Table 2 Seasonal climate clusters of representative locations

City	Cluster	Size (%) <i>N</i> = 365	Humidity ratio (g/kg)	<i>T</i> (°C)	GHI (KWh/m ² /day)
Keylong	CL1	25.2	0.6	−6.68	488
	CL2	19.2	0.8	−4.24	613
	CL3	30.4	1.78	6.08	730
	CL4	25.2	4.29	15.02	747
Kullu	CL1	33.2	5.65	12.25	534
	CL2	9.3	8.61	18.9	573
	CL3	25.5	8.67	22.98	737
	CL4	32.1	14.89	24.84	740
Manali	CL1	23.3	3.28	3.38	490
	CL2	20	3.98	7.52	603
	CL3	32.3	6.67	15.66	730
	CL4	24.4	10.89	21.99	749
Naggar	CL1	17.5	3.92	5.49	480
	CL2	22.5	4.86	9.53	579
	CL3	27.7	6.96	17.92	719
	CL4	32.3	12.27	23.97	747

cluster mean values during winter (cluster 1 and 2) and is prevalent for about 44% of the year. This season is accompanied by low solar radiation (cluster mean of 488 KWh/m²/day) and very low humidity. On the other hand, Kullu (CZ11) experiences moderately cool winters with cluster mean value of 12.25°C (cluster 1) which is prevalent for about 33% of the year. However, the daily minimum temperatures dip below zero during a few days in this cluster.

Fig. 4(a) presents the statistical summary of daily mean temperatures with respect to the climate clusters for the four representative locations. **Fig. 4(b)** presents the statistical summary of solar radiation with respect to the climate clusters for these locations.

Fig. 4(c) shows a psychrometric plot of daily mean temperature and humidity data of Keylong and Kullu. Keylong (CZ5) experience a dry severe cold weather. Kullu (CZ11), which borders the composite climate zone to its south, experiences moderate and cool weather.

Fig. 4 Statistical summary of (a) daily mean T_a (b) daily mean solar radiation, for seasonal clusters. (c) Psychrometric plot of clustered ambient weather data for Keylong and Kullu.

Thermal Adaptation in Cold Climate

In last few decades, researchers around the globe started questioning the rationale of static comfort models developed in laboratories and gave rise to alternate theories. This resulted in the theory of adaptive thermal comfort (Brager and de Dear, 1998). The adaptive comfort theory is based upon the approach that if change occurs such as to produce discomfort, people react in ways which tend to restore their comfort (Nicol and Humphreys, 2002). This approach is based upon the field studies surveys in the real world. Thermal comfort field studies conducted across the globe established that people are flexible and adapt their behavior to make them thermally comfortable. The adaptive hypothesis states that one's satisfaction with an indoor climate is achieved by matching the actual thermal environmental conditions prevailing at that point in time and space with one's thermal expectations of what the indoor climate should be like (EN15251, CEN Standard, 2007). In field studies, surveyors collect the thermal responses from the subjects. Simultaneously environmental data is recorded based on class I, II, III protocols. This information needs to be statistically evaluated and validated for the significant relationships between neutral temperature and air temperature (EN15251, CEN Standard, 2007). Humphreys found that indoor air temperature is an outcome of outdoor temperature. In naturally ventilated buildings static comfort models predicts thermal sensations different than the occupants actually feel. Adaptive comfort model reveals that the thermal comfort temperature is a function relating to the outdoor air temperature

Table 3 Adaptive equations

Comfort equation	Source
$T_{comf} = 0.31T_{out} + 17.8$ (1)	ANSI/ASHRAE (2004)
$T_{comf} = 0.33T_{rm} + 18.8$ (2)	EN15251, CEN Standard (2007)
$T_n = 0.22T_{out} + 17.86$ (3)	Singh <i>et al.</i> (2011)
$T_n = 0.54 * (30 \text{ day } T_{rm}) + 12.86$ (4)	Manu <i>et al.</i> (2016)
$T_{rm} = (1 - \alpha)\{T_{od-1} + \alpha T_{od-2} + \alpha^2 T_{od-3} \dots\}$ (5)	Nicol and Humphreys (2010)

(Yao *et al.*, 2009). Fanger (1993) states that the best buildings for overall comfort either provide conditions that are within the accepted comfort range for most occupants most of the time (so people do not need to change things that much) and/or people have the facilities to alleviate discomfort quickly when it occurs. Chappells and Shove (2001) state that "Comfort is a highly negotiable socio-cultural construct". This provides a classic definition of adaptive thermal comfort criteria. With the changing outdoor temperature from season to season use of adaptive models in naturally ventilated buildings gains significance. Researchers across the globe have conducted such studies in a variety of climates to establish comfort limits. A review of literature reveals that adaptation is affected by their cultural and socio-economic lineaments.

Empirical equations for estimation of adaptive thermo-neutral temperature and comfort temperatures are presented by ASHRAE based on the extensive studies by de Dear and Brager (Eq. (1)). Similarly, EN15251 came up with an equation based on exponentially weighted averaged running mean temperature, which takes people past thermal history into account for the estimation of T_n (Eq. (2)). The concept of running mean temperature (Eq. (5)) is based on Nicol and Humphreys (2010). The authors state that the exponential weighting system results in a decay in the importance of any past temperature with a half-life in days. They emphasize that monthly mean temperature can be variable within a month, resulting in changes in the neutral temperature through short-term adaptation. Hence, the use of the running mean outdoor temperature provides a realistic representation to adaptive comfort model (Table 3).

An equation for operative comfort temperature indoors for buildings by Singh *et al.* (Eq. (3)) for cold climate of Northeast India based on field study for naturally ventilated buildings is used for determining the neutral temperature. The study was based on vernacular buildings of northeast India. Manu *et al.* carried out adaptive thermal comfort studies for multi climatic zones including cold climate of India and estimated the T_n based on equation (Eq. (4)). The T_n varied from 19.6°C to 28.5°C.

Factors Affecting Thermal Adaptation

Physiological adaptation

The core temperature of human body needs to be maintained within close limit of 37°C for the proper functioning of human body. The brain sends or receives the signal, which acts as a controlling mechanism in case of thermal discomfort. Vasoconstriction is initiated when the body temperature falls. Similarly, vasodilation happens when the body temperature gets high. Over a period of time, the effect of strain caused by heat and cold gradually decreases by exposure to these extreme temperatures by human body in order to be in thermal balance. This physiological adaptation is a result of long time and short time physiological adaptation. Long time physiological adaptation is a result of genetic adaptation, which is developed from generation to generation. Short time physiological adaptation is result of acclimatization, which happens within one generation. However, time required to acclimatize may differ from a single day to years.

Psychological adaptation

People's past and current thermal history has a great role on their thermal expectation. It is the unconscious thermoregulatory reaction. The thermal sensitivity diminishes if repeatedly exposed to a certain thermal environment, which induces relaxation in thermal expectation.

Behavioral adjustment

Behavioral adjustment is an outcome of people's cultural habits, social and economic status. It accounts for clothing's that they wear, food they eat, activities they do. This can be consciously or unconsciously done on a daily basis to keep their body in thermal balance. These adjustments are classified in three subcategories-Personal (putting on or taking off the clothing), technological (turning on/off radiators or tandoors) and cultural (traditional woolen attire, evening tea) Fig. 5.

Adaptive Limit in Cold Climate of India

Adaptive thermal comfort limits

Fig. 6(a-d) shows the thermal comfort limits for the representative locations estimated on exponentially weighted running mean temperature (Eq. (5)) (Nicol and Humphreys, 2010).

Category II represents the moderate thermal expectations of $T_n \pm 3^\circ\text{C}$ and UL (Upper limit) and LL (Lower limit) provides the comfort limits for this category (EN15251, CEN Standard, 2007). Considering the ambient temperatures prevalent at these

Fig. 5 (a) A typical living room in contemporary building in Manali (Cz5), (b) A living room cum kitchen in a traditional building in Keylong (CZ5), (c) A living room cum kitchen in contemporary building.

Fig. 6 Adaptive thermal comfort limits for (a) Keylong (b) Kullu (c) Manali (d) Naggar.

Fig. 9 (a) Traditional and (b) Contemporary settlements in cold climate (CZ5).

locations, the indoor temperature needs to be within these bands as per the adaptive comfort model. The category I and category III that represents high and low thermal expectation. In order to make dwellings thermally comfortable, thermal performance of buildings needs to be regulated to keep indoor temperature inside these comfort bands.

Field Surveys to Evaluate Thermal Adaptation

To check the extent of thermal adaptation in the Indian cold climate, a field study has been conducted in Kullu (CZ11), Naggar (CZ9), Manali and Keylong (CZ5). The studies were undertaken during post-summer (September to October 2017), winters (November 2017 to February 2018) and summer (June 2018). Two types of surveys – Longitudinal and transverse surveys are administered along with physical measurement of indoor and outdoor thermal variables. In longitudinal surveys, the selected respondents are surveyed over one-week duration on thrice-daily basis (during morning, noon and evening). Transverse surveys are right-now, right-here kind of surveys, which are administered to ensure a wider coverage of samples. The bilingual questionnaire was prepared in Hindi (native language) and English. Surveys have been administered while they were seated indoors. Simultaneously environmental data including indoor temperature T_a , relative humidity (RH), air velocity (V_a) and globe temperature (T_g) were measured. The readings were recorded at 1.1 m from floor level using Delta OHM thermal comfort meters (Fig. 5) (accuracy $\pm 0.35^\circ\text{C}$, $\pm 2.5\%$ RH, ± 0.05 m/s for 0–1 m/s V_a and ± 0.15 m/s for 1–5 m/s V_a). A total of 1561 samples were

Fig. 10 A typical traditional Kath-kuni dwelling in cold climate, Manali (CZ5).

Fig. 11 (a) Typical vernacular and (b) Modern dwelling in cold climate, (CZ5).

collected from residential buildings in Kullu, Naggar, Manali and Keylong. A stratified random sampling method was adopted to include all of the prevalent building (traditional and contemporary) typologies.

The thermal sensation votes are averaged for every 1°C of indoor temperature bins. Fig. 7 shows the correlation between mean thermal sensation votes (TSV) and the corresponding mean indoor air temperature (T_{in}) for the Indian cold climate. The neutral temperature is determined by obtaining regression equation at mean TSV equal to zero. T_n established through this study is 23°C which is similar to the already conducted studies in cold climate of northeast part of India (Singh *et al.*, 2011).

Fig. 8 shows the iso-lines of neutral temperature evaluated on the basis of estimated neutral temperature. The range of T_n is found between 13 and 24.5°C for whole of cold region. Except for extreme cold climate of upper Lahaul and Spiti and some parts of Kinnaur in Himachal Pradesh, most of the settlements has neutral temperature in the range of 17–22°C. For upper Himalayan settlements having extreme winters T_n is found to be on lower side than most of the settlements (CZ5, CZ9, CZ11) within range of 18–23.5°C. It needs to be noted that, ground studies in the extreme cold desert regions are essential to validate the above estimates.

Buildings in Cold Climate

Vernacular buildings in cold climate of India exhibit an evolved climate response. They offer time-tested examples in terms of construction materials, techniques and spatial design, which are further customized with people's adaptive life style. This section focuses on residential settlements in the state of Himachal Pradesh, India, which displays CZ1 to CZ11 sub classification of cold climate described earlier in this chapter. The terrain of upper Himachal Pradesh is mountainous in nature making its elevation variable throughout the state.

Fig. 9 shows (a) the traditional and (b) contemporary settlements. These buildings are located in compact clusters, which restricts the flow of cold winds. The building materials and techniques vary based on the local thermal severities. However, climate responsive strategies such as use of thermal mass, orientation to garner winter solar gain are identical across the region. The traditional construction technology like "Kath-Kuni" (Fig. 10) is prevalent in most of the rural dwellings in which alternate layers of wood and stone masonry in an interlocking manner.

Kath-Kuni structures are prevalent in CZ11, CZ9 and parts of CZ5 deodar wood and stone is being used in abundance. These dwelling have a sloping roof covered with thick stone slates supported by wooden beams. These building are generally of 2+1 floors.

Fig. 12 A contemporary dwelling in severe cold climate, Keylong (CZ5).

Fig. 13 Plan of (a) traditional house (b) contemporary house in Naggar (CZ9).

Fig. 14 Comparison of T_{in} and T_{out} for a vernacular and modern house in Naggar (CZ9).

Table 4 Climate responsive design applied in traditional dwellings in Indian cold climate

Region Illustration	Climatic zone	Strategies	Climate responsive design
L&S	CZ5	Trapping heat during the day and release during the night ● Reduce time to warm up area ● Reduce heat loss to exterior environment Passive solar gain	
	Cold winds	● Compact form ● Low floor to floor height ● Small opening in other than north wall ● South orientation ● Large opening in south wall ● Dark colored wall ● No sunshades	Large South Facing Windows
Kullu and Manali	CZ11, CZ9 and CZ5	Cold Winds ● Unilateral window to avoid cross-ventilation	Unilateral Opening (Limits Wind Flow) Bilateral Opening (Enhances Cross-ventilation)
		● Wooden screen to outside walls ● Low floor height ● Compact form ● Heat generation from livestock through the infiltration and internal gains to subsequent floors	

The floors are of wooden planks rested on wooden beams which are cantilevered to all sides to provide balcony space which is used as a storage as well as semi-outdoor space. The ground floor generally used as cattle shed and to keep fodder. This shed also helps to keep adjacent floors warm during winters. The buildings have very narrow openings to resist heat loss. The middle floors serve as living and bedroom. The attic space generally has kitchen and granary store and also provides thermal barriers to the other floors. The 600 mm

Kath Kuni wall with alternate layers of wood and stone provides high thermal mass. Some buildings also incorporated mud plastering to make them more efficient. Moreover, the floor height is less than 2.7 m so as to reduce the air volume inside.

In severe cold zone (CZ5) (Fig. 11) building are made of thick mud plastered stone masonry wall construction. Buildings in CZ5 (Lahaul and Spiti region) have high thermal mass and are made up of minimum of 600 mm stone masonry with mud mortar. These walls are mud plastered and need occasional maintenance. The houses do not use much of wood like kath-kuni houses as the region lacks in good quality of wood suitable for construction. These houses differ in roof constructions as majority of them has a flat roof. These roofs are made up of thick mud mortar and gravel mixture casted into a slab that rest on wooden beams. This roof provides high thermal mass, which also restricts heat loss when these are covered with more than 700 mm of snow during winter.

The contemporary buildings (Fig. 12) have adapted the RCC framed construction technique with stone masonry cement plastered wall insulated with wooden paneling from inside. The building with 230 mm Brick plastered wall generally has stone cladding from outside. The thickness of cladding varies from place to place. Generally, people go for 7–10 cm thick dressed stone as clad (including mortar). Some houses also incorporate wooden paneling over ceiling. In these houses' roofs are generally Reinforced concrete exposed or covered with galvanized iron sheets. The wooden openings are bigger in comparison to traditional buildings.

A real-time monitoring of indoor and outdoor thermal conditions performed during summer and winters in CZ9 (Naggar) is presented further. The measurements correspond to a vernacular house (H1, Fig. 13(a)) and a contemporary house (H2, Fig. 13(b)). H1 has a traditional Kath-Kuni system with 600 mm thick external walls with mud plastering. Floors and ceilings are constructed with 25–30 mm thick wooden planks, which allows some infiltration between adjacent floors. The roof consists of stone slates rested on wooden beams, which absorbs solar radiations and traps that into attic. The floor-to-floor height is 2.7 m. H2 is a reinforced concrete frame construction with 230 mm brick plastered external walls and internal wood cladding. The floor-to-floor height is 3.5 m.

Fig. 14 shows the measured T_{in} and T_{out} of H1 and H2 during 5–10 October in 2017. Diurnal range of T_{out} varies between 9°C and 16°C. The maximum temperature during the day rise up to 25°C while it drops till 9°C in early morning hours.

Despite this fluctuation in T_{out} , T_{in} remains stable within both of the houses; however, vernacular kath-kuni dwelling, H1 experiences less temperature swing than H2. H1 has a longer time lag (about 8 h) compared to H2 (3–4 h). In terms of overall thermal comfort measured in terms of Fanger's PMV, the vernacular house (H1) outperformed the modern house (H2). During winter, PMV varied between –0.3 and –0.9 while in summer it varied between +0.6 and +1 in the vernacular house. In the contemporary residence PMV varied between –0.6 and –1.5 during winter and +0.6 and +1.5 during summer. This depicts the suitability and performance of the vernacular buildings and the importance of bioclimatic strategies adopted in these buildings to suit in this particular climate. Table 4 summarizes the climate responsive design strategies used in this region.

Fig. 15 Required strategies based on Mahoney's method (a) Opening size, and (b) Roof.

Fig. 16 Bioclimatic design strategy zones of the north indian cold region.

Table 5 Climate zone and bioclimatic strategies of selected locations in the Indian cold climate

City	Climate zone	Bio-climate Zone	Window size	Position of openings	Walls/Floors (Heavy, > 8 h time-lag)	Roofs (Heavy, > 8 h time-lag)
Keylong (L&S)	CZ 5	BZ 10	Composite (20%–35%)	Has no climate related values	Yes	Yes
Udaipur (L&S)	CZ 5	BZ 10	Composite (20%–35%)	Has no climate related values	Yes	Yes
Kaza (L&S)	CZ 5	BZ 10	Composite (20%–35%)	Has no climate related values	Yes	Yes
Manali (Kullu)	CZ 5	BZ 9	Composite (20%–35%)	In N and S walls at body height including Internal walls	Yes	Yes
New Manali (Kullu)	CZ 5	BZ 12	Small (15%–25%)	In N and S walls at body height including Internal walls	Yes	Yes
Jana (Kullu)	CZ 5	BZ 12	Small (15%–25%)	In N and S walls at body height including Internal walls	Yes	Yes
Naggar (Kullu)	CZ 9	BZ 12	Small (15%–25%)	In N and S walls at body height including Internal walls	Yes	Yes
Kullu	CZ 11	BZ 12	Small (15%–25%)	In N and S walls at body height including Internal walls	Yes	Yes

Bioclimatic Classification

Olgyay *et al.* (2015) emphasized that general forms of buildings are more influenced by the climate. Bioclimatic design refers to the careful selection and application of passive & energy efficient building strategies to provide a comfortable indoor environment under given climate conditions (Labaki and Kowaltowski, 1998). It aims to take advantage of the climate conditions and delineate recommended building strategies for a certain region (Wan *et al.*, 2010; Pawar *et al.*, 2015). Since the term bioclimatic design came to use in the domain of architecture, it adopted various methods of assessing the interaction between human comfort requirements, climate conditions and building design. Most notable are the bio-climatic charts by Olgyay (1963), the building bioclimatic charts (Givoni, 1976) and the Mahoney tables (Mahoney *et al.*, 1971). In this section we present a Mahoney method based bioclimatic classification of the study region.

This comprises of three steps. Step one involved computation of annual mean temperature (T_{Au}) from mean of the annual maximum and annual minimum temperatures. The outside monthly maximum and minimum temperature, mean monthly relative humidity, and monthly precipitation data (30'' spatial resolution) are referred from worldclim (Fick and Hijmans, 2017; New *et al.*, 2002). Step two involved

- (1) Calculating monthly temperature range ($T_{\text{max}} - T_{\text{min}}$),
- (2) Creating T_{Au} groups ($< 15^{\circ}\text{C}$, $15\text{--}20^{\circ}\text{C}$, and $> 20^{\circ}\text{C}$),
- (3) Categorizing the relative humidity into four groups (below 30% = G1, 30%–50% = G2, 50%–70% = G3, and above 70% = G4,
- (4) Determining upper and lower temperature limits for daytime and nighttime comfort by comparing humidity groups with T_{Au} groups,
- (5) Diagnosing thermal stress through comparing temperature values with the upper and lower comfort limits (C=cold, O=comfortable, H=hot) and
- (6) Identifying three humidity (H1, H2, H3) and three aridity (A1, A2, A3) indicators.

Step three involved identification of design recommendations from the annual summaries of humidity and aridity indicators. For example, the layout (orientation) of a building can be north to south either if A1 occurs for less than 11 months or if A1 happens for 11 or more months followed by A3 more than four months.

Fig. 15(a) presents the required window-to-wall ratio. As shown, neither large nor very small windows are necessary. Fig. 15(b) shows the required thermal mass of roofs. It is clear that light roofs are not suitable across all cold climate regions.

Individual bioclimatic strategies tend to show uniformity across vast areas with the exception of opening size (strategy-d), position of openings (strategy-e), walls and floors (strategy-g), and roofs (strategy-h) which are responsible for the huge variabilities in the final output (Fig. 16). Table 5 presents the detail climatic and bioclimatic characteristics of selected locations. It also highlights detail strategies of size and position of openings, and envelope thermal properties. Due to the geographical proximity of the selected locations, most of them appear in the same zone.

Summary and Conclusions

The chapter discussed the thermal severities and climatic diversities in cold climate of north Himalayan region. A rational approach was presented through which the cold climate zone was sub-classified into eleven sub-zones (Fig. 3). Climate data of representative locations were statistically analyzed to verify the significance of diversities (Fig. 4(c)). Such sub-climate zones can be regionalized to district administrative boundaries in order to facilitate effective implementation of building thermal regulation and energy efficiency codes. Physiological, psychological and behavioral thermal adaptation in cold climates was presented with relevant field examples. Adaptive comfort limits based on T_{rm} was discussed for representative locations. Results of adaptive comfort field study carried out in this region was presented. T_n established through this study is 23°C which agrees well with similar such studies conducted in cold climates. T_n isopleths were presented (Fig. 8) for the cold climate region based on this study. Vernacular housing practices including construction systems were presented and their thermal performance were compared with contemporary houses through real-time measurements. Geo-spatial data of this region was used to create a bioclimatic classification based on Mahoney's method. Based on this analysis, the study area was classified into thirteen bioclimatic zones. A comparison of some of the vernacular housing practices with that of the bioclimatic strategies was presented. The bioclimatic architecture adapted in vernacular housing provides a learning to adopt these strategies in contemporary buildings to make them suitable for the habitants in this climate.

Traditional Crafts as Materials in Placemaking: Application and Sustainability in Aesthetic Transformation of Geometry of Urban Public Spaces

Jayati Mukherjee, National Institute of Fashion Technology, Patna, India

Mainak Ghosh, Jadavpur University, Kolkata, India

Traditional Crafts and Materials

Crafts are as inherent to any traditional society like food, shelter and clothing. It gives it the cultural identity which is uniquely identifiable by its aesthetics and materials. Crafts and craftsmanship remains one of the oldest occupations which a community used for fulfilling purpose and also to create appealing spatial compositions. Settlements that go well into various historic periods are treasure trove of these crafts. The significance of crafts as materials will be discussed in the context of India, being one of the oldest settlements with a heritage of amalgamation of cultures across periods and retaining its ethnic identity manifested through harmonious coexistence of religious and social practices (Balaram, 2011).

History of the Crafts – Tradition and Relevance in Social Context

The socio cultural heritage of all civilizations manifest through their crafts. Rooted in social practices and traditions, it becomes part of the aesthetic expression of a community. As knowledge is handed over from generation to generation, crafts become a part of its intangible heritage. Going back into the evolution of the human race, all activities, be it hunting or farming, building shelter or making clothes, crafted objects have fulfilled the basic needs-every product an expression of creation. The artisanship worked on indigenous materials, form and function going hand in hand on the need to design-within the parameters of the locale and the society. Social practices in terms of religion, culture, ethnicity helped retain the identity of a craft, allowing it to survive through ages (Ranjan and Ranjan, 2014).

Across cultures, the crafts have enriched communities with their aesthetics although the purpose may have been similar. These aesthetics give the identity of the community and being distinctly differentiable from one to the other. Considering a strongly material based craft such as Woodcraft. We see it manifested in the various cultures whether in the form of the Noah's Ark or the Temple of King Solomon. Egyptian Pyramids hold them in various forms of furniture with a protective finish as well. Wood was even imported to compensate local resource. The Romans used it more as a construction material or furniture with carvings. In the Middle ages it turns to entire buildings and large sculptures. In Central Asia, we find building elements and intricate crafting which later was adopted for stonework. The skill varies in the Orient where, while in China we get exquisite precision based small day to day objects, in Japan it is best expressed in intricate scenery and curved or bent wood work and special joinery is seen. With the development in hand tools, techniques and the property of timber available, we see the variety in wood craft across the world. But the objective across the cultures remained to create elements to improve the space with objects which were durable, usable and good to look at. These objects defined the space and gave it its character through the craft. So the design identity remained the same within a region though materials differed- as seen in the motifs from China engraved in wood and stone (Figs. 1 and 2).

Practices and Applications – Materials and Process

The ethnocentric characteristic of many old societies and communities have relied on traditional wisdom which shaped over generations of using the five elements in materials. Thus, whether we use a material in raw form for daily use or process it for products developed for keeping for generations, depended on the knowledge of daily practices and the trial and error methods of ages.

Each community gave shape to its crafts in the way that suited their lifestyle. While the objects of daily need remains similar in form and use, like a pot, the materials, tools and physical environment largely determined the form. The crafts bore the signature of the culture and varied across the section of this vast land. However, strangely remaining united in the purpose but differing in motifs and designs. Thus, although they both use natural elements for jewellery making, the Maoris of New Zealand carve it into organic forms while the Native Americans would use it to embellish metal jewellery (Sentance and Sentance, 2009) (Figs. 3 and 4).

According to the definition adopted by the CCI Symposium/CCI Symposium "Crafts and the International Market: Trade and Customs Codification", Manila, 1997 "handicrafts are the ones produced by artisans, either completely handmade or with the help of manual or mechanical tools, as long as the direct manual contribution of the artisan remains the most substantial component of the finished product. Handicrafts are made without restriction in terms of quantity and using raw materials from sustainable resources. The special nature of artisanal products derives from their distinctive features, which can be utilitarian, aesthetic, artistic, creative, culturally significant, decorative, functional, traditional, religiously and socially symbolic and significant." This is an expression of the materials and the creative process of arriving at the optimum solution by indigenous routes. For all traditional crafts, local materials and techniques are the only mode of expressions, crafted by hand. The artisan communities work like guilds. A bamboo is cut raw for daily use container produced instantly, but naturally processed to make boxes or pouches for storing valuables able to withstand natural decay of centuries. Materials that are available in a region remain the primary material for prototype and tools and techniques appropriate to shaping the same has varied degrees of craftsmanship. It is the ingenuity of the creator, the artisan, which elevates the form from ordinary to a revered one-each product

Fig. 1 Wood craft – Wild Goose Pagoda, China. Courtesy Prof. Rupkatha Mukherjee, BKG College, Kolkata.

Fig. 2 Stonecraft – Forbidden city, China. Courtesy Prof. Rupkatha Mukherjee, BKG College, Kolkata.

speaking its purpose. The traditional and time tested processes reveal in the survival of the product form over all these years. The terracotta pot survives side by side with stone pottery as a successful design appropriate to the locale.

Decadence – Sustainability

Traditional crafts are less adaptive to industrialization and contemporary aesthetics. Urbanization and advance of modernity leads to marginalization of something as ethnic that may be confused with rural. New materials and newer processes lead to greater production and saves time too. New generation of traditional clusters digressing to newer pastures for better life leads to slow death of the traditional wisdom which needs nurturing and practice for continuity. Contemporary lifestyle and spaces opt for modern products and tradition is thrown to winds. In the process enlarging the carbon footprint left behind. People tend to choose these appropriate to the purpose of the times which have evolved largely away from the tradition. The clay pot or metal jug being replaced by the bottle, an industrial product. Apart from Industrialization, Globalization acts as a leveller in erasing ethnic characteristics and creating a global society uniform across the earth (Jaitly, 2012).

Renewal/Diversification – Crafts as Resource

Crafts remain a regional activity and grow with the regionality. It imbibes the essence of the climate, geology, flora and fauna of the locale, as also the colours, patterns, language, practices, activities that are part of the ethnicity of the community practicing the craft. The older the heritage of a region, more diverse is its crafts. These crafts become essential to the way of life. The reason why Oriental societies exhibit the vibrancy of crafts in daily life and space. Regions not having indigenous races are bound to lack this identity as settlements from

Fig. 3 Maori fish hook pendant – New Zealand. From Wikipedia & Creative Commons.org.

Fig. 4 Navajo stone & metal Jewellery – USA. From Wikipedia & Creative Commons.org.

outside the region would take longer time to build its heritage. Crafts need to grow over time, which is only possible in civilizations which have a larger span of survival in history. It may have several cultures merging, but in order to be an integral part of the lifestyle, manifesting in all possible ways, it needs the consistency and stable progress to become the identity. This is perceptible as seen in the visual character of traditional houses in Kyoto varying distinctively from those in Venice, lining up on water channels (Figs. 5 and 6).

In spite of rampant Industrialised growth of societies, moving from villages to cities, there is a natural tendency in human minds to retain their ethnic identity. And this is largely possible by retention of crafts in human spaces and life. In a contemporary world, crafts are needed, but in order to survive the times, crafts need to be expressed differently. Craft materials need to venture in new avenues and create appropriate solution. The renewable characteristics of the materials helps in building a resource with longer life which is environment friendly. The same logic plays in using the traditional products in new uses seeking new areas where technology can help in its inclusion in innovative way (Ranjan and Ranjan, 2014).

As crafts are expression of frozen time, it is the same way that it needs to be viewed as an exploration and solution for present needs. After all, we cannot see a modern glass clad skyscraper in China with Pagoda style roofs, except as an Architectural disaster. There lies the need to attain a balanced state of the old and the modern standing side by side, not necessarily mixed. Regional identity is visible in the rock cut Architecture of two world locations cited below (Figs. 7 and 8).

Significance of Traditionally Craft Rich Regions – Example, India

India is diverse in its socio cultural systems as well as bio-diversity, climate etc. Resulting in varied use of materials in the crafts symbolic to the region it belongs to. Thus the boldness of the artefacts of Jammu and Kashmir reflects the hardship of crossing the mountains, while the mica in the sands of Gujrat initiates exquisite mirror work of the region (Jaitly, 2012) (Figs. 9 and 10).

And the use of material varies from place to place as seen in distinctly different forms like the geometric iron tribal figurine of the Bastar region standing apart from the ornate bronze Chola temple figurines (Ranjan and Ranjan, 2014) (Figs. 11 and 12).

Fig. 10 Mirror work, Gujrat. Available at: <http://gaatha.com>.

In a country of myriad hues and forms, India remains a treasure trove of crafts generated out of languages and dialects, religions, ethnic groups, tribes, castes and sub-castes, festivals and over 1 billion people, half of them living in the villages, spread from the ocean to the Himalayas, with mountains, valleys, plateaus, deserts, backwaters, forests and even inhospitable regions. With millions of craftsmen and innumerable craft clusters, traditional crafts remain till date the biggest experience with indigenous materials and their sustainability. The versatility of use of these materials for appropriate applications speak largely of the ingenuity of its creators (Ranjan and Ranjan, 2014).

Although most of the crafts may be termed as people's art, more stylized forms have generated out of religious practices. The Hindu caste system have indirectly retained the identity of each craft by segregating the artisans in professional groups. Although socially marginalizing, it restrained craft practices and skills within selective social groups, and transmission of the knowledge from generation to generation. Instead of losing out to evolving times, this helped retain the identity of the craft, its materials, tools and techniques, with gradual changes infiltrating with Industrialization and globalization only. This has broad based the crafts from major practices like pottery, weaving, metal craft, stone craft, bamboo craft etc. which are largely material based, to more skill oriented ones like mural, painting, glass work etc. India lives in its villages. So a craft practiced today may be sidetracked later but will continue to sustain in a locality to support local need. It is this fluidity and reach of a craft combined with the expanse of the practice of crafts in India, which makes it nearly impossible to encompass its possibilities and reach (Jaitly, 2012).

Fig. 11 Tribal figure, Bastar. Available at: <https://www.outlookindia.com/outlooktraveller>.

Fig. 12 Bronze figures, Chola temples. From Wikipedia & Creative Commons.org.

Being a civilization dating more than 5000 years, with multiple invasions leading to amalgamation of cultures, the crafts of India have sustained its essence and process, evolving over the inclusive nature of society adopting other cultures and keeping up to the pace of change. The crafted goods remain testimony to the cultures and practices imprinted in the materials reflecting the roots of the social system that produced or used the object. Crafted forms developed for daily use has remained as basic material manipulation with functionality. While the ceremonial ones reflected the intricate aesthetics again as possible with the available resource of materials and tools used to its finest expression (Ranjan and Ranjan, 2014). Moving between regions of the country one gets to see the similarity of practice while differences in manifestation- as seen in the Alpana in the East to Rangoli of North or Kolam in the South, all three being ritualistic creative patterns on the floor, done by hand, with materials differing (Figs. 13–15).

In this age we have crafts dying for various factors. Stone carving remains restricted to temples only as transportation is a deterrent. Hence the craftsmen shift to other occupations. Without patronage and also due to conservation and preservation, many of the expensive materials like Ivory, Sandal wood crafts have become near extinct (Ranjan and Ranjan, 2014).

Tradition and modernity need to co-exist side by side in the modern times. Indian crafts are designed with ecological sense, based on renewable or eco friendly materials, resulting in aesthetics befitting natural surroundings. In keeping pace with modernity, these need to transform into contemporary design and use. While tradition retains its values, newer expressions are required for market acceptance. Being a rich culture of festivals, traditional crafts still occupy the bazaars in and around religious activities as the aesthetics go hand in hand with the cultural actions. It is this aspect that needs to be worked upon to make the craft viable, marketed through contemporary platforms of fairs, trade shows illustrating their diverse possibilities.

Fig. 13 Alpana – West Bengal. Available at: <https://in.pinterest.com>.

Fig. 14 Rangoli – Delhi. Available at: <https://in.pinterest.com>.

Fig. 15 Kolam – Tamil Nadu. Available at: <https://in.pinterest.com>.

Being a land of paradoxes, social patterns remain deep rooted and cannot be standardized. Physical diversity differs from mental perceptions, leading to completely different sensibility in terms of colour, aesthetics etc., may it be the sober palette of the southern lush green states to the vibrant hues of the western arid regions, India defies all norms of standardization. Growth and evolution in society has led to change in the caste system to the class system, bringing in the need for appropriate design solutions to the new necessities. In a country with agriculture as a primary economic activity, crafts play a major role in exports. As a renewable resource material, crafts can play a vital role in diverse uses. Rural spaces have always had an aesthetic legacy using indigenous techniques and judicious use of local materials. In urban spaces, use of crafts gives direction to Architectural design and planning of spaces. Crafts can be used in urban spaces with ingenuity as shown below using mud-mirror craft of Kutchh, also known as 'Lipan Kaam' (Balaram, 2011) (Figs. 16 and 17).

Experimental uses of clay plates in ceilings or natural textile based wall panels have yielded in improving micro environment within the closed spaces. Diversifying into the public spaces and its aesthetics to reduce the mundane character, adding vibrancy that only crafts can bring, is commonly seen in shaping the cultural ethos of Indian society through its festive celebration.

Methodology of Study

The methodology adopted for the research activity conducted may be illustrated as below

Fig. 16 Traditional house interior. Available at: <http://gaatha.com>.

Fig. 17 Office exterior. Available at: <https://engrave.in/blog>.

Application and Relevance of Traditional Crafts and Materials in Spaces

Traditional crafts have always been a part of creating spaces, as the elements that make a space, were crafted only. The locale and its resources always defined the space in terms of its form and the materials and techniques generated the look. In the Indian context, the diversity is stunning and all encompassing, leading to unique experiences as one moves from one region to another (Ranjan and Ranjan, 2014).

Selection of Craft – Relevance w.r.t. Aesthetics

Indian crafts suit Indian conditions of climate, handling etc. It is optimum in terms of use of resource and meeting the purpose. Traditionally art and craft work as a unified whole. Through these crafts, rural spaces transformed into reflection of the culture. Thus every craft had its own identity expressed through its looks and the character given to the space it belonged to. It also is an expression of the craftsmanship. The refined and cultivated products such as wood carving are classic while the basic forms like papier mache toys remain equally delightful. Their individual visual character makes it appropriate to its application and characterising space in turn.

Each regional culture has its objects, colours, outlines defining its spatial character. It ranges from deep interiors to open outdoors. The space created reflecting the geographical and climatic needs of the community as well as the cultural identity built over ages. Mythology plays a significant role as religion remains embedded deep in the hearts of the people. Hence aesthetics of the craft emerges in objects which reflect this association in form and spirit. The walnut wood carvings or products, the motifs of leaves and flowers derived from the nature around, or the motifs derived from the silk trade woven into the carpets makes it an identity as Kashmir beyond question. Naturally a wooden house as theirs or the house boat is expectedly adorned with these crafts. While just some distance away in a similar regional location, Ladakh remains distinctly different in terms of the colour and motifs of its pile carpets, metal embossed objects to stitched boots. The crafts complementing the spaces created out of stone. The essence of religion creating the so perceptible diversity. Thus when selecting an object of either region brings with it its unique identity stamped into the crafted product and demands or enriches spaces to imbibe similar aesthetics (Ranjan and Ranjan, 2014) (Figs. 18 and 19).

Diversification of Design and Use – Sustainability

Traditional crafts have remained in the locality of origin naturally for the sake of availability of as the resource material. But it has also moved out to other corners of the country or across the world seeking newer markets for generating employment by practice of the craft.

Fig. 18 Knotted carpet – Kashmir. Sourced from Ranjan, M.P., Ranjan, A., 2014. Handmade in India. Mapin Publishing. pp. 31, 41, pdf – Scribd.

Fig. 19 Pile carpet – Ladakh Sourced from Ranjan, M.P., Ranjan, A., 2014. Handmade in India. Mapin Publishing. pp. 31, 41, pdf – Scribd.

The global shift towards indigenous and organic products and the green movement has forced attention back to crafts as alternative to industrialised products. May it be spatial structure or system, or decorative value addition, or cosmetic changes, physical spaces have undergone changes with reintroduction of crafts. The vibrancy and natural feel of the material is easy to associate with. It is the physical form which needs to be contemporised to adapt to the changed social system. Thus the jute gunny bags and handicrafts modify to wall panels or murals transforming the interior into a simplistic modern space with a rustic feel good in insulation.

With a populace as diverse as possible in its mentality, the demands, both physical and aesthetic, are a myriad of choices, colourful or colourless, vibrant or sober, hard or soft, detailed or flat, and so on. It is only crafts which are readily available, as a multifarious form suiting personal demands, to transform the spaces as envisaged by design intervention, diversification or simple alternate use. Crafts are generally used in interior spaces as accessory or cosmetic change, selected from product displays from craft bazaars at random to match the decor or as a wish. Such collection is bound to have short life of use, likely to be thrown away after a time. Such products are also made with lack of sincerity by the crafts person as it fails to be considered a heritage. But if the entire space is conceived to recreate an ethnic identity, the craft item becomes an integral component. It becomes structural to the aesthetics, not a value addition to a somewhat related interior or space. Craft materials can sustain in the future when we start looking at it as a component of built space- as it was at the inception and for centuries down. This needs a complete reorientation of the design, contemporising the look and purpose, using newer techniques for quality and longer life span, yet not compromising on the essence of the craft itself. The Art of Craft needs to move out of one's own room to the public domain for greater acceptance and reach.

Environmental Implications – Recycling Materials

Industrialization and non bio degradable objects are the biggest threat to the human race. Though we have replaced the glass in the chandelier with acrylic, we did not learn what to do with the waste when we throw it away. Crafts are built on materials born out of the region or nature. Hence, it is from the soil, is tolerant to the climate and goes back to the elements after living its life. The craftsman understands the material with fondness and has the necessary rapport as he or she grows up moulding it in their hands

and feels. The attachment is so strong that the material also unfolds itself in the hands. The creation is built to die a natural death after its purpose is complete. Thus the environmental impact of crafts have always followed the green code. As the production has been need based, there has been little surplus to consider a wastage. This is so contrary to the mass production of industrialised items (Jaitly, 2012).

India is a country of up cycling and down cycling. It is common to households to pass down objects and utilise it to the full, until it dies its death. Indian philosophy of saving resources and austerity has always been integral to lifestyle. The example of a Saree converted to Kantha for longer sustenance of the material is just one example. Crafts have always been the avenue for recycling materials and components into daily use objects. For ceremonial purpose, purity of the product remains primary though. But post celebration, the same artefacts can be reused as inherent to the objectivity of the craft (Figs. 20–22).

Urban Public Spaces

Public spaces are different from culture to culture, in terms of its use. Irrespective of their background, they are used as social spaces which is naturally accepted by the community around. In urban areas, it is more of defining the purpose and segregating the spaces

Fig. 20 Traditional Bengali saree. Courtesy Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

Fig. 21 Recycled saree to Kantha throw. From Wikipedia & Creative Commons.org.

Fig. 22 Designer Nakshi Kantha saree. Courtesy Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

as per activity. It is expected to generate social interaction, for festivities and celebrations where cultures intermix. It is these interaction and engagement of citizens in public domain that makes the space come alive. Public spaces are inclusive. But in countries like India with deep cultural heritage, we see the traditional city remaining side by side with the formal city. So, in absolute harmony, the planned geometric public spaces of the new city with specific uses co-exist with the organic free flowing ones of the old city with multiple uses. Walking the streets in Delhi, one can savour the lineage of the Mughal era in Old Delhi with its organic planning and meandering lanes, while in stark contrast New Delhi carries the stamp of the colonial Era in Lutyens' grid layout with vistas and strict geometric planning (Gupta and Gupta, 2016).

Spatial Structure – Activities and Uses

Public spaces are defined by UN-Habitat as “all places, including streets, publicly owned or of public use, accessible an enjoyable by all for free and without a profit motive”.

Urban public spaces in developing countries are free flowing organic conglomeration of shapes. It has its memories and nostalgia of its own. It is a direct opposite to the urban planning of the West and defies rigidity of boundaries. Urban public spaces are dehumanised in terms of use as compared to rural multifunctional public spaces.

As Architect Charles Correa said – ‘a City without shared public spaces is a City without culture, without history.’

In an urban context, space is a resource-used for functional, ritualistic, social, political and cultural interchanges. Public spaces, which developed naturally, are pockets of activities arising out of the need of the surrounding built environment. The unplanned growth results in interesting volumes and shapes which can be assigned separate functions which are more personal and can induce closer interaction. Public spaces transform itself to suit different activities at different time of the day. A busy business area by the day transforms itself into a sleeping quarter for the urban poor at night. This is in contrast to the urban spaces of planned cities which have pre-determined uses and shape, lacking the versatility in terms of its use. Irrespective of its origin, the space remains a place where complete strangers can participate in camaraderie, forgetting their social or community positions (Correa, 1985).

Chaos and Order – Identifying Aesthetic Entropy

Urban public places have always been a place to meet and exchange, may it be Greece, Italy, Africa or India. In order to celebrate the interaction, all public places have always been a composition of aesthetically appealing built elements. So from the proportion of the Agora, to the beautifully crafted column capitals, to the flea markets or to the neighbourhood square, aesthetics and its associative factors have always been the limits which create order and disorder combined to a vibrant composition. This array in disarray tend to leave a longer mark in the heart of the viewer. In the context of urban areas, one needs to appreciate the order in this chaos which allows the space to break the monotony. Under this chaos, communities live and organize themselves. It marks its physicality within its own set of social conventions (Correa, 1985).

The variety of activities result in a multiple stack of objects and elements in a public place as in India. Lack of Defined Symmetry, Ordered Geometry of the space results in sets created as if out of different planes, opening, boundaries. To this adds the various objects correlated to the activities performed. So a linear space such as a road through business area lined with shops and bustling with people from outside in the daytime, turns into a sleeping quarter for the pavement dwellers, vendors, porters of the locality or maybe the vagabond, by night (Critchlow, 1976).

But the visual space remains studded with the store hoardings, shutters, waste bins in tandem with the covered boxes of the street dwellers' belongings, with an occasional towel or shirt hanging on a hook. A bustling work space in the day turns into an open residence after business closes. On weekly day off, with shutters drawn, the same space changes its aesthetics with maybe the entire laundry of the users hanging from temporary clothes line or owing to an activity camp for the street children (Fig. 23).

The dynamics of these Indian organic urban public spaces produce an aesthetic entropy of the highest level as nothing remains constant. The absence of rigid defined vertical or horizontal lines, grids, helps to bring in transition of visual movement from one point to another. Multiple persons, activities, objects of use together create visual frames that is never constant and keeps on changing. The chaos adds vibrancy to an otherwise mundane urban space. Sub spaces within the space are created by different materials. A flex banner becomes a shade from rains. Apparently chaotic and unsystematic and random arrangements of these finally attain a state of repose. It is a different aspect whether the inherent entropy creates aesthetically pleasant compositions (McCall *et al.*, 2005).

Fig. 23 The entropy of public spaces in Kolkata. Courtesy Mr. Diptarag Bhattacharya, COO, Amway, Gurugram.

Role of Community in Placemaking – Culture and Use of Public Space

The result of the chaos and eventual order also induces a need to improve on visual quality which is difficult to achieve within a regular daily schedule. Indian culture is inclusive. Indians embrace all religions and communities with the same warmth and festivals are celebrated together. Indian community is an interactive one, equally in good and bad times. Public spaces transform into Community spaces during the festivals. Durga Puja of Kolkata being the biggest testimony to this transformation. During this festival the community participates in the Placemaking as a reflection of the local community's assets, inspiration or expression. It results in complete transformation of a mundane daily work/living space to quality spaces which contribute to the happiness and well being of the people who use it. People collectively visualize and reinvent the public space and gives it a new feel for a few days, when festivals happen. Everyday dull spaces are transformed into a different realm, based on the potential of the space in terms of its geometric structure scale and built volume. Reflection of specific culture comes out through the common Theme (Spreiregen, 1965).

Any festival celebration is done in the public spaces as per its own parameters and norms. Culture plays a strong role in redefining the space Durga Puja being the biggest of all in India, especially its eastern region, it brings in participation of all communities- following Hindu traditions with modern expressions. With time and the change in urban culture, it is expected to transform with modernity in looks with deep rooted religious ethos. The transformation may represent another space and time, creating a new aesthetic entropy (Montgomery, 2003).

Geometry of Urban Public Space Inducing Aesthetic Transformation With Crafts

The rigid geometry of a planned city differs from the fluidity of an organic space in a traditional settlement. This allows the latter to undergo a variety of aesthetic transformations as would be needed for social purposes. The transformation in consideration of festivals is to be discussed in the context of Durga Puja in Kolkata, which is majorly an organic city, with major shortage of community spaces. This is significant as the festival is a minimum 5 day ritual and the festivities and the associated transformation remains for a period of 10 days with pre and post festival activities. It is indeed remarkable to see an urban public space with a completely different purpose temporarily transforming itself for that many days with complete community acceptance. Such an exercise remains rare and unparalleled across nations (Maslow, 2013).

Geometric Structure of the Public Space w.r.t. Space Transformation

Urban Public spaces can be classified into some common shapes, which defines the transformation for Placemaking of pandals during Durga Puja. The city in consideration for the study being Kolkata (Correa, 1985).

These would be –

- (1) *Linear: broad* – A main street-passage lined with boundaries created out of buildings, railings, walls. The side structures characterized according to residential, commercial, business, industrial, institutional uses. The feel of space as narrow or long characterized by the scale of built structures around. Passage for pedestrians and vehicles, even buses, need to be left. This allows the visual frames to be created for appreciation, majorly from inside and also outside (Fig. 24).
- (2) *Linear: narrow* – A lane-passage lined with boundaries residences and walls, in a predominantly residential space. The feel of space being narrow and private, generally blocked to vehicles with narrow passage for pedestrian entry into the houses around. For enjoying at close distance, very personal (Fig. 25).
- (3) *Rectilinear: on thoroughfare* – A wider space at crossroads-roads or lanes allowing bigger congregation. Passage for movement to be maintained and visual compositions can be directional. Can be a focal point from outside (Fig. 26).
- (4) *Rectilinear: at dead end* – A community space in use-directional movement to reach the structure. Both vertical or horizontal emphasis may be given to form (Fig. 27).
- (5) *Junction: T shaped* – Roads or lanes on 3 sides-visibility needed from all sides but the back. Passage of people and cars in the front creates directional viewing. The built structure should remain closer to eye level for observation (Fig. 28).
- (6) *Junction: L shaped* – Street corner. Importance as Node and structural aesthetics will demand angular viewing (Fig. 29).
- (7) *Free: closed* – A park or community space with walls or railings. Boundaries and gates define the passage within the transformed space (Fig. 30).
- (8) *Free: open* – A field or vacant plot in locality with or without boundaries. The pandal structure can be located at convenience with activities around. Such partitions allow for asymmetric arrangements. Existing built space around decides the direction and focal points (Fig. 31).

Identifying Entropy for Application of Crafts/Materials

Each of the above spaces already have their own aesthetics. In the transformative activity of crafting the theme pandals, the physical boundaries may or may not be put to use, but the horizontal free space is marked as usable space and structures created around them. The vertical elements at the side can be interestingly included and merged into the design theme. The created entropy is vibrant and dynamic enough to deserve attention for the duration of the pujas and leave a lasting impression

Fig. 24 The structures allow movement through or on one side. From Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

Fig. 25 The space would always appear vertically taller. From Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

Fig. 26 A larger built form with visibility from all directions. From Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

Fig. 27 Importance of façade. Passage leading to like an axis. From Ms. Jayati Mukherjee, Assoc. Prof., NIFT.

Fig. 32 Concept of theme Pandals reflecting materiality. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

beyond the period too. People tend to remember for long the compositions by virtue of the ordered arrangement of elements implanted into a completely different visual space as also the entropy generated by the movements of visitors. The static sets built with crafts and the dynamics of human movements with a purpose completely different to the public space concerned leaves a lasting impression of cultural experience, of chaos and order (Gupta and Gupta, 2016).

As the intended placemaking involves recreating a different space, built on crafts, the concept evolves on the craft and its elements and colours. Hence each horizontal or vertical space represents a composition with the crafted products. The material of a craft being its foundation of expression or the process of shaping the material into the end product, the space eventually reflects the material property in all possible forms and becomes a creation on material property only (Weeks, 2010) (Fig. 32).

Use of Materials for Creative Placemaking

Crafts and crafted products are entirely dependent on its material and technique of manipulating the same into feasible products of use. The use may be utilitarian or decorative, which is also a use. Crafts come in various forms. But there are some general ways of using or creating which is visible in these pandals (Ching, 1996).

The types which are largely seen being—

- (1) *Structural elements* – Beams, columns, pillars, posts, joists, trusses, roofs.
- (2) *Units* – Walls, partitions, panels, tiles, ceiling, backdrop.
- (3) *Frames* – Entrances, openings, objects, patterns, racks.
- (4) *Lighting* – Chandeliers, spot, focal, illumination.
- (5) *Hanging* – Bells, ceiling decor, flying objects.
- (6) *Lifestyle* – Pots, utensils, mats, furniture.
- (7) *Recreated* – Real life objects in other forms like weapons, tools, books, instruments.
- (8) *Decorative* – Patterns, textures, shapes, forms, artwork.
- (9) *Communicative* – Real life models, material manipulation, graphics, semiotics, narrative.

Some creative material usage of traditional crafts are illustrated below Figs. 33–40:

In the above typologies the crafts are used in traditional forms as well as modified contemporary designs. Scale of prototypes remain close to the craft practiced as the artisans working on this recreation is deft with the practice passed through generations, their craft remaining cultivated and well-honed to meet the taste of urban clientele. Although design modifications or diversification are introduced, it is difficult for them to change the techniques much for improvised products. Neither is it essential as the essence and flavour of the craft would then go away. Thus, retaining the tradition of the craft, the design takes its shape in the skilled hands of these craftspersons (Balaram, 2011).

Feasibility Study of Application of Crafts and Materials in Transformation of Urban Public Spaces

In a multicultural country like India, religion remains integral to urban spaces, mutually influencing community activities. Contrary to being a secular space, a Contemporary city is a cross religious visual realm. In turn imbibing the need to create a physical space and structure serving as key focal point, even if temporary (Gupta and Gupta, 2016). The product semantics of India remain as ancient as the vedas. The artefacts derive from everyday life and have become part of the cultural and hence religious identity. The crafts became an identity of territoriality and symbolic of the ritualistic character of space for application

Fig. 33 Bamboo. Courtesy Mr. Arnab Paul & Mr. Rupayan Biswas, Alumni, NIFT.

Fig. 34 Wood. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

Fig. 35 Metal utensils. Courtesy Mr. Arnab Paul & Mr. Rupayan Biswas, Alumni, NIFT.

(Balaram, 2011). Hence for any religious space created, even temporary, like a Durga Puja Pandal, crafts become integral to create a space for attention and reverence which is not achievable through Industrial materials.

Urban spaces are often given makeovers with craft objects added as decoration only during events or promotions. Urban areas have become spaces which lack the identity which is typical of a traditional space where crafts remain integral to the space. In this context, it needs to be reviewed how much transformation of an urban space may be possible using crafts and materials to create a uniqueness which stands apart from the adjoining brick, glass, plastic clad mechanical aesthetics. The geometry of the spaces need to be worked upon to understand the application of the crafts and how interesting spaces emerge from it (Carmona *et al.*, 2010).

Case Study – Community Durga Puja Pandals, Kolkata

A study of Durga Puja in Kolkata conducted over years show how a location in the busy City of Joy changes its aesthetics in so many different ways by use of crafts. It is interesting to note that every year the concept changes dramatically for the same space

Fig. 36 Terracota. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

Fig. 37 Cane. Courtesy Mr. Arnab Paul & Mr. Rupayan Biswas, Alumni, NIFT.

Fig. 38 Coconut. Courtesy Mr. Arnab Paul & Mr. Rupayan Biswas, Alumni, NIFT

and the visual perception of the space based on use of these crafts create an identity so diverse from other years, while the geometric structure remains the same.

Crafts and materials are used in creative and varied ways. Traditional Materials used primarily being Wood, Bamboo, Cane, Metal, Fabric, Yarn, Clay, Plaster of Paris, Glass, Paper along with thermocol, plastic and recycled material.

Geometric structure of the space

It gives the direction of visualizing the change possible in that space and the final realisation of the composition leading to a transformation of the physical spatial volume introducing crafts and materials. The case studies cited below pertains to leading

Fig. 39 Wooden toys. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

Fig. 40 Patachitra. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

Durga Puja Pandals in Kolkata and the periodic change in forms over years will show the transformation in terms of the geometry of the space perceptually viewed in varying manner in the same urban space context (Ching, 1996).

- (1) Tridhara Sammilani–
Visually wider space in 2013 by using intricate crafts, enhancing verticality (Figs. 41 and 42).
- (2) Mudiali Club–
Experimenting with space enclosures and scale (Figs. 43 and 44).
- (3) Badamtala Ashar Sangha–
To bring uniqueness in a general residential neighbourhood (Figs. 45 and 46).
- (4) Barisha Club–
Complete change in format – open and closed (Figs. 47 and 48).
- (5) Ballygunge Cultural Association–
Focus shifted from viewing from outside in 2013, highlighting external space in 2014 to highlighting interiors in 2016.
Scale enhanced (Figs. 49 and 50).
- (6) Shibmandir–
Playing with creative use of materials (Figs. 51 and 52).
- (7) Nalini Sarkar Street–
Very narrow lane requiring creative space design (Figs. 53 and 54).
- (8) Jodhpur Park–
From community Puja pandal with basic decoration to crafted spaces (Figs. 55 and 56).

Other factors related to transformation

Apart from physical space, the placemaking considers some other factors which are inclusive in the transformation of the space. It includes the built and unbuilt aspects of the space.

- (1) *Scale* – When wider space or visibility from a distance is possible, majestic scales are introduced, while in other spaces more human scale is applied (Figs. 57 and 58).
- (2) *Surrounding elements* – These are included in the conceptualization and become a component in the space created Fig. 59.

- (3) *Application of Light* – Creative lighting leads to complete change in the visual perception of the space designed (Figs. 60 and 61).
- (4) *Detailing of craft used* – Meticulously executed intricate detailing of the craft can recreate traditional spaces Fig. 62.

SWOT Analysis

Strength

Craft materials are largely sustainable and renewable in nature, Hence the materials and prototypes can be conveniently adapted to different uses when the present spatial arrangement undergoes change. e.g., a daily use metal Pot can easily become an element of the structure. Similarly, a craft object like a bell can be put to use in a lampshade.

(a)

(b)

Fig. 49 (a) Location of Ballygunge Cultural Association (courtesy Google Map). (b) Direction of Geometric transformation (Courtesy Ms. Jayati Mukherjee, Assoc. Prof., NIFT).

Weakness

Craft products and materials mostly come with a short life or with susceptibility to wear and tear. In order to emerge as an alternative material in public spaces which would remain exposed to external environment as well as handling by different people, In order to make it sustain, the materials need to be relooked into or its application reinvented using latest technology.

Fig. 52 Shibmandir in (a) 2010. (b) 2012. (c) 2013. (d) 2016.

Opportunity

Using crafts in public spaces open up a vast avenue for revival of the crafts as it comes as an expression of a highly creative form in an urban domain allowing the urbanite to patronise the craft and help it come back. Not only does the craft product improve the aesthetics of the space but also gives it a newer dimension breaking the monotony of a staid urban space otherwise so formal in its character. Crafts, by virtue of their details, colours, features add dynamism to the space.

Threat

Lack of practice has led to a dearth of skilled hands who can actually produce highly creative end products and scarcity of experts on the physical and behavioural properties of a material used in a craft, which was inherent to the master craftsmen who would pass on the knowledge and skill as inheritance. This leads to development of prototypes which are either mixed or created with more commonly available materials. These would lack the finesse and uniqueness of the original craft, having visual similarity, resulting in an inferior imitation.

Impact Analysis of Use of Crafts and Materials

Contemporary spaces use new age materials which are industrial products and are diametrically opposite in character to traditional materials. The materials bear the stamp of their production and are impersonal and mechanical in the perception they create. The scale of these spaces are very different from traditional spaces too. Thus, the perception of urban spaces are formal, strictly geometric, somewhat rigid and largely impersonal except maybe for private and personal spaces like residence etc. It has a

Fig. 56 Jodhpur Park in (a) 2012. (b) 2013. (c) 2015. (d) 2017. Courtesy Ms. Anwesha Mukherjee, Student, NIFT.

Fig. 57 Monumental scale. Arnab Paul & Rupayan Biswas, Alumni, NIFT.

Fig. 59 Adjoining building facades painted, coloured and crafted according to the theme. Courtesy Dr. Bishnupriya Basak, CU, Kolkata.

universal identity not exclusive to any region or culture. The scale used is often monumental as these spaces are for public use. Verticality overrules horizontal spread due to dearth of land available vis-à-vis use (Harlan, 1986).

Traditional crafts, by their origin, have an innate rustic or rural characteristic which may not work well with urban or contemporary aesthetics. But the traditional materials and crafts are more environment friendly and the visual perception to use in

Fig. 60 Transformation through light effect – Day and night. Courtesy Dr. Bishnupriya Basak, CU, Kolkata; Courtesy Ms. Anushka de Choudhury, Psychologist, Kolkata.

spaces were developed over time possibly through trial and error to achieve the best possible result. The scale of these objects are more human and easy to relate to.

The use of these crafts in the Durga Puja activities show that they can

- (1) Transform an otherwise mundane impersonal space into a vibrant personal one leading to community involvement.
- (2) Induce identity to spaces, bringing in a human scale to formal areas too.
- (3) Increase entropy of the space drastically which leads to initiating positive interaction and action so necessary in a busy urban life.

Some examples of this Entropy can be seen as below where crafts play the role of creating the vibrancy inherent to it (**Fig. 63**).

Future Implications/Directions

The study based exercises reveal a very interesting direction in the application of crafts. The traditional aesthetics of design is retained as that is the flavour and uniqueness of the craft.

Materials

Introducing the craft in a different place would fail for deficit of raw material. But the cases above reveals a mix of prototypes generated with new age materials along with traditional ones. The new materials introduced have greater sustainability and are worked with the same finesse to produce the form (Figs. 64 and 65).

Design

Considering the sensibility of a contemporary world, the design of the prototypes are creatively evolved into a composition of forms merging the crafts with visual character as is expected in traditional designs. The same detailing with its exquisiteness is available in the end product (Figs. 66 and 67).

Technique

In the absence of skill set owing to decadence in practice, newer technologies can be introduced to generate similar effects and also can lead to greater production due to time saving (Figs. 68 and 69).

New directions

In order to appeal to the generation of youth who are less aware of crafts as materials with their tremendous scope of application, newer methodology is required to adapt them to the aesthetics of crafts and materials (Fig. 70).

The analysis of transformation of the geometry of the urban public space reveals that this could be a major initiative to introducing crafts in urban spaces, both personal and public. Crafts can be introduced not as a cosmetic treatment but as a complete makeover of both exterior and interior spaces. It can initiate revival of the traditional prototyping with interventions in time oriented designs, adopting new materials and technology-bringing back material in a space having greater sustainability, environment friendly solutions, and allowing recycling.

Sustainability of Materials in Temporary Space Making

Use of materials in Durga Puja Pandals of Kolkata are of temporary nature. Assembly and dismantling of materials happen over a few days only. While the sourcing and assembly is meticulously worked out with adequate time to execute the details and to ensure the final aesthetics of the space created, the dismantling is done in haste and leaves behind a residue of leftover waste

materials. While major stock of materials are either reused or recycled, the craft materials are largely reused as decorations or sold after the event, while the waste materials are left over and require to be removed as garbage.

The primary materials and their different applications as used in a pandal are listed below –

(1) Bamboo – Available locally, biodegradable

<i>Application</i>	<i>After use</i>
Structure	Reused
Decorative crafts	Reused/sold

(2) Cane – Generally sourced, biodegradable

<i>Application</i>	<i>After use</i>
Decorative crafts	Reused/resale as craft

(3) Wood – Available locally, biodegradable

<i>Application</i>	<i>After use</i>
Partitions	Reused/reconstructed in furniture
Structure	Reused in construction, furniture
Woodcraft	Reused/sold

(4) Fabric – Different types that include cotton, silk, jute and polyester, generally biodegradable

<i>Application</i>	<i>After use</i>
Covering/sheath	Reused/recycled
Decorative designs/prints	Reused

(5) Yarn – Coir, Jute, cotton, silk, biodegradable

<i>Application</i>	<i>After use</i>
In structure	Reused
Decoration/crafts	Reused/sold

(6) Paper – Various types, biodegradable

<i>Application</i>	<i>After use</i>
Panels/partitions	Reused
Decorative designs/artwork	Reused/sold
Crafted items	Reused/sold / recycled

(7) Plastic – In both soft and hard form, non-biodegradable

<i>Application</i>	<i>After use</i>
Acrylic sheets as panels	Reused
As Flex sheets for graphics/	Reused/recycled
Thin sheets as fabric, decorative designs	Reused by pavement dwellers
Crafted decorations	Reused
Small available items such as cups, plates, spoons etc.	Recycled/waste

(8) Thermocol – As sheets, blocks, products, non-biodegradable

<i>Application</i>	<i>After use</i>
Panels/partitions	Reused/waste
Decorations, small items	Recycled/waste

(9) Metal – As sheets, wires, pipes films, some are non-biodegradable

<i>Application</i>	<i>After use</i>
Panels/partitions	Reused
Decorations and crafts	Recycled/waste
Layering of objects	Waste

(10) Clay – As pulp or granular form, biodegradable

<i>Application</i>	<i>After use</i>
Surface design	Waste
Sculpting and crafts	Recycled/waste

(11) Plaster of Paris – As pulp or granular form, semi-biodegradable

<i>Application</i>	<i>After use</i>
Panels/skins	Recycled
Sculpting and crafts	Recycled/waste

(12) Terracota – As solid products, biodegradable

<i>Application</i>	<i>After use</i>
Panels/units	Reused/sold
Decorations and crafts	Recycled/sold

(13) Natural fibres/articles – Sholapith, reeds/grass, shell, coconut shell, seeds dry flowers – Biodegradable

<i>Application</i>	<i>After use</i>
Crafts and decorations	Recycled/sold
Panels/units	

(14) Glass – Sheets/units, semi-biodegradable

<i>Application</i>	<i>After use</i>
Panels	Reused/sold
Products/crafts	Recycled/sold

(15) Paint – Natural dyes or Emulsion, acrylic, synthetic enamel – toxic, non-biodegradable

<i>Application</i>	<i>After use</i>
Natural dyes on crafts	Recycled waste
Industrial paint finishes	Non-recycled waste

The above tables clearly illustrate that in consideration of sustainability, the natural materials and crafts are way above industrially produced materials. The craft materials are generally completely biodegradable or otherwise reused as products or similar purposes, or sold as a craft product owing to exquisite craftsmanship, or recycled into mix-media products. This helps sustain the crafted products and materials for a much longer duration, eventually reducing depletion of resources of Earth, continuing to exist in diverse forms over longer duration, during While the industry produced raw materials continue to be responsible for enhancing the carbon footprint on the Earth. While, on the other hand, materials produced by industrial systems continue to add to the non biodegradable mass of waste products. This justifies the use of crafts and natural materials in temporary structures, like Pandals, even more, and the same may be emulated for permanent spatial structures and buildings or built spaces, leading to reduction in piling of man-made waste generated by the building industry.

Materials as above, used in these temporary spaces, can be broadly classified into the following domains –

- (1) Natural/Man-made.
- (2) Reusable/Non-reusable.
- (3) Bio-degradable Waste/Non-biodegradable Waste.

The materials listed in above tables may be interpreted graphically as –

SL. NO.	MATERIAL	NATURAL	MAN-MADE	REUSABLE	NON-REUSABLE	BIODEGRADABLE WASTE	NON-BIODEGRADABLE WASTE
1	BAMBOO						
2	WOOD						
3	CANE						
4	FABRIC						
5	YARN						
6	PAPER						
7	PLASTIC						
8	THERMOCOL						
9	METAL						
10	CLAY						
11	P.O.P.						
12	TERRACOTA						
13	NATURAL FIBRE/ ITEMS						
14	GLASS						
15	PAINT						

It clearly shows how sustainable natural materials are w.r.t. their properties. Crafts, being born out of natural materials, thus play a vital role towards sustainable design and reducing environmental degradation.

Conclusion

“The purpose – where I start – is the idea of use. It is not recycling, it’s reuse” – Issey Miyake

Design in the context of contemporary urban space need to be relevant to the needs of a developing country like India and be resource saving and employment generative. And it must befit the physical and social needs of the people- expressing respect towards sensibilities, comfort, tastes and sustenance. Realisation of design through local materials and skills naturally imbibes all the factors leading to a successful product or experience that can be replicated and remains accepted by the community in concern. Handicrafts, having been a component of the daily life, is tested over time and is innovation from the roots of a culture, besides being a means of livelihood for generations. Incorporating crafts and materials into public spaces and activities in a diversified contemporary way can bring vibrancy into the spaces, build sense of association related to the perception in its aesthetics, and show new directions for traditional employment using newer technology in hand.

The building materials domain can be relooked into for being inclusive on crafts and materials, resulting in creating unique spaces with an identity of its own which brings back traditional practices and social actions. In an era when the world emphasises the need for going back to the roots, it is important to review the implication of this as it transforms space, and space is to be interpreted and put to use with multi-dimensionality. Considering the youth of the society, who form the majority of population and live in today, creating awareness would lead to sustenance of crafts and infuse new life into these age old professions. It will help revive the crafts as alternative materials for creating interesting visual spaces- rich in its vibrancy and with dynamics that is inherent and an essential expression - the unique identity which arises only from crafts. The experimental experiences in the Theme Pujas of Kolkata definitely indicates the possibility.

Understanding High Performance Buildings: The Link Between Occupant Knowledge of Passive Design Systems, Corresponding Behaviors, Occupant Comfort and Environmental Satisfaction

Mili Majumdar, Green Business Certification Institute, India and U.S. Green Building Council, Washington, D.C., United States

© 2020 Elsevier Inc. All rights reserved.

What is a High Performance Building?

Buildings are designed and operated to function for a purpose. The purpose may be vary and hence design and operational parameters also vary from one building to other. By way of example, commercial office buildings and residential buildings have very different function and purpose. While a high performing office building shall be designed and operated to provide high level of occupant comfort with lower energy and other resource consumption, residential buildings have more diverse requirements in terms of personal needs and variation of space type within the residence. A high performance building shall be designed to perform at high level of all functional parameters. It shall provide optimum level of comfort at minimum energy cost and consumption. For purpose of this article, *we are limiting the discussion to energy and comfort only, though water and waste minimization, recycle and reuse, materiality of a building are equally important for delivering a high performance building.*

Optimised energy consumption, with desirable thermal, visual and acoustic conditions to meet occupant comfort, good quality of air and other indoor environmental parameters all contribute to high performing buildings and occupant well-being and productivity. High performance buildings need to be operated as per design, and hence occupant knowledge of systems and maintenance and monitoring holds key to maintaining high performance through life cycle of the building. To define high performance buildings let us first define key design strategies and approaches that support such buildings.

The energy consumption in a building can be reduced through a multipronged approach. The key steps are:

- Reduction in energy demand
- Use of on site sources and sinks and use of passive systems
- Maximise system efficiency

Reduction in energy demand is a function of architectural design, optimising needs and use of onsite sources and sinks. The building skin or envelope plays a dominant role in this effort. The building envelope protects its occupants from heat of sun, rains, and provide a comfortable environment for work and leisure. Use of space conditioning systems to keep occupants comfortable and use of lighting systems to provide visual comfort is a necessity in most buildings. High performance buildings aim to reduce these requirements and thus reducing the intended energy use, without impacting comfort. Reduction in energy demand entails adoption of design measures to reduce space conditioning, lighting and service water heating loads. The first step to reduce energy demand is to design for the macro and micro climate of the site by adoption of suitable bio-climatic design principles. As suggested by the name itself, bio-climate design varies from one climate zone to other. For example, India has six climatic zones ranging from extreme cold conditions in cold desert of Leh, Ladakh to extreme hot and dry conditions in Rajasthan. A building in a cold climatic zone has to adopt measures to harness the sun to maximum extent by adoption of measures like maximum exposure to south, windows to capture heat, dark colored surfaces, high thermal mass and insulation to retain the captured warmth of the sun, or use of design elements such as trombe wall, sun spaces etc. On the other hand, a building designed for a hot climate would have measures to reduce solar gain like, smaller window sizes, shaded walls, minimum exposure to west and east, external wall and roof insulation or use of design elements like solar chimneys, wind towers, etc to maximise ventilation (**Fig. 1**).

Use of onsite sources and sinks offers wide opportunities for energy savings in a building. Site microclimate is an important aspect that makes building designs in the same climatic zone, distinct from one another. Each building site would have distinct topography, vegetation, wind flow pattern, solar and daylight access- and the design response should be able to address the site requirement. Thus two buildings located in the same climatic zone may have different design features due to varying microclimate. For example in an unconditioned building, design and placement of window according to site wind regime can reduce energy requirement for mechanical ventilation.

Take the example of the office building *Sangath* (**Majumdar, 2001**) of the renowned Pritzker prize winning architect from India Shri BV Doshi. An architectural studio, it is designed to naturally manage the forces of nature. There are spatial, constructional and landscape responses to combat the vagaries of nature in the hot dry climate. For Ahmedabad with summer temperature reaching up to 45°C, sun is very intense and the natural comfort conditions can be achieved by protecting spaces from heat and glare. It is the sun rather than breeze that becomes critical.

The design responses to the same are as follows:

- Subterranean spaces
- Storage walls

Fig. 1 Large south facing windows for solar gain in cold climate of Leh Complex, India.

Fig. 2 Sangath, Ahmedabad, India.

- Vaulted form of the roof
- Sandwiched construction of vault (the vaulted roof is of locally made clay fuses over the concrete slab which provide less-conductive layer; the top finish of china mosaic glazed tiles further enhances insulation property by being white and glossy to reflect sun and being of clay to retard heat transmission; Indirect/Diffused Light; North-glazing)
- Micro-climate through vegetation (Lawn and vegetation cover all around create favourable micro-climate by absorbing solar radiation and providing cooler passage of air through humidity)

These features and many more have ensured excellent climate control within in terms of keeping inside cool and increasing time lag for heat transfer. There are about 8°C temperature difference between interior and exterior of the roof skin temperatures. The time-lag is nearly six hours (Fig. 2).

Passive systems provide thermal and visual comfort by using natural energy sources and sinks, e.g., solar radiation, outside air, sky, wet surfaces, vegetation, and internal gains. Energy flows in these systems are by natural means such as radiation, conduction, and convection with minimal or no use of mechanical means. The solar passive systems vary from one climate to the other. Knowledge of passive systems by occupants is important to enable appropriate operation of the system and derive benefits in terms of energy savings. Let us take the example of Trombe Walls used as a passive walling system to capture solar energy in a thermal mass during daytime and use the stored energy as a source of space heating at night. The Trombe walls are usually vented to avoid excessive heat build up and allow for convective flow of heating energy into the space. However, if the vents are left open at nighttime, the convective currents shall allow cold air to move to the spaces indoors, thus causing thermal discomfort.

Passive systems or combination of passive and active systems have conventionally been able to reduce energy consumption. These systems, once applied need to be well understood by occupants so as to derive benefits of their application. For example,

Daylighting is effective provided it is devoid of glare and occupant knowledge of same is necessary to take advantage of daylight. Some commonly used passive concepts that help reduce energy use in buildings are:

- Proper orientation of buildings (in the northern hemisphere, the most desirable orientation would be to have the facades and fenestrations facing south and north with minimum exposure to east and west);
- Proper placing and designing of windows and their sizes (windows should be optimally designed for daylighting and high percentage of glazed surfaces should be avoided in hot climates);
- Suitable design of louvres/sunshades; proper provision of natural light inside the buildings to reduce the initial and recurring cost of providing artificial lighting systems;
- Insulation, provision of thermal mass, reflective surfaces to reflect radiation etc.

Building energy codes and standards provide recommended envelope and system efficiency parameters for design of energy efficient and high performance buildings. Ashrae 90.1 2010 or later editions provide standards for minimum energy performance in buildings and is followed as an international best practice. Local equivalencies with national building energy codes can be established and followed for design of high (energy) performance buildings e.g., India has its own Building energy code, ECBC 2017 that applies to commercial buildings.

Maximising system efficiency offers further opportunity for energy savings. Use of efficient lighting, air conditioning and service water heating systems can reduce energy use in a building by 30%–40%.

Designing High Performing Buildings: The Key Components

The above section defines the key principles of designing and implementing a high performance building. However, the first principle to achieve objective of a high performance building is to have a coordinated and integrated team that will deliver the same. Integrative design is the first principle to high performance building wherein performance goals are to be set by building users and owners. The goal setting on performance is followed by an integrative approach to deliver the design goals. However, a building should be operated as designed to realise the benefits of a high performance design. Hence the bridge between design and operation is crucial to ensure a building remains high performance throughout its life cycle. The following diagram summarises the steps to achieve and maintain high performing buildings (Fig. 3).

In addition to setting performance metric at overall energy consumption level, performance and/or design metric may also be defined at a component level of building envelope (e.g., thermal transmittance values for walling, roofing, glazing and solar heat gain coefficient of glazing), and at system level for electrical, lighting and HVAC systems. For each system there could be performance metric and design metric at component level or at whole system level.

The following diagram provides a summary of performance parameters that holistically contribute to higher performance as far as energy utilization is concerned (Figs. 4 and 5).

Setting Design and Operational Goals for High Performance Buildings

The first step to high performance buildings is to set design and operational goals. Performance metric in high performance buildings is a combination of metric for:

- Energy (connected load and consumption)
- Water (consumption/capita and source apportionment to fresh water, recycled and reused water and quality of water)
- Waste (reduce waste generation and reuse/renew/recycle waste)
- Comfort (thermal, visual, acoustic)
- Air quality

In this article we have focussed only on energy and associated comfort parameters. Water and waste optimisation and performance is not in scope of this article.

Defining Energy Performance in High Performance Buildings

Energy performance is usually defined by unit of energy consumed in terms of kWh per unit area of space (sqm) over a given period of time, usually over a year. The lower the consumption, the better the environmental impact of the building. Energy consumption in a building varies largely from one to another and is determined by climate, geography, cultural context, economic level, level of technologically advanced systems incorporated, individual behavior and use. There has been an increasing push towards lowering energy intensity in building energy use through passive design, technological advancements in systems design and renewable energy integration in buildings. Highly energy efficient residential and commercial buildings have a total energy intensity of 50–100 kWh/sq m of floor area/year, compared to a typical value of 200–400 kWh/sq m/year (GEA, 2012: Global Energy Assessment: Towards a Sustainable Future, Cambridge University Press, and IIASA, Austria). High performance calls for

Fig. 3 Steps to a high performance building.

Fig. 4 Some key building components that have a role in high energy performance design.

moving towards a net zero regime in energy use, which essentially requires the consumption to be offset by on site/off site renewable energy. Annual average solar irradiance ranges from 160 W/sq m in middle latitudes to 250 W/sq m in sunniest regions. The potential of generating renewable energy through use of solar will depend of available shadow free area on roof or other suitable surfaces, and thus net zero energy consumption in a building is highly subjective of the location, size and use of the building, other than buildings that have access to off- site generation of RE. U.S Green Building Council (USGBC) has announced Net zero certification for LEED certified projects wherein exemplary projects with any one of the following: net zero carbon emissions, net zero energy use, net zero water use or net zero waste can aim to be Net zero certified.

Fig. 5 Key systems that contribute to high energy performance design.

There is a deep co-relation between metric set for Indoor environmental conditions such as level of desirable thermal and visual comfort and metric set for energy consumption. Usually it is inversely correlated. For example an office building designed in hot climate with lower set of temperature e.g., 22°C will have higher energy consumption than if the same space was designed with adaptive comfort. Let us review a few parameters for setting comfort related performance benchmarks for high performance buildings.

Thermal Comfort (U.S. Green Building Council, 2013)

Thermal comfort in a space greatly impacts health and productivity of occupants. It is a cumulative impact of surface temperature, air temperature, humidity, air movement metabolic rate and clothing. Modifying one or more of these factors can greatly influence occupants' comfort perception. ASHRAE 55-2013 or higher is widely followed as a reference standard for setting thermal comfort goals in a space. Other commonly followed standards are ISO 7730 or CEN standard EN 15252, latest version. Thermal comfort is also a personal requirement and varies across individuals. Occupants who are able to modify their thermal environment through thermal controls shall perceive more comfort. Thus a high performance building allows occupants to regulate comfort, thermal and visual through use of effective control strategies to regulate comfort.

Following steps should be adopted to for effective thermal environment in a high performance building:-

- (1) Establish thermal comfort goals. The designer and owner should set building wise and space wise goals for indoor conditions and variations.
- (2) Select space conditioning system to meet the thermal comfort goal. The space conditioning type should be selected based on thermal comfort goals. Natural, mechanical or mixed mode are three common types of space conditioning. Design of natural or mixed mode strategies require careful design considerations of external climate and corresponding indoor conditions that is desirable. However, natural and mixed mode buildings can offer higher level of energy savings through careful planning.
- (3) Select comfort controls. Choose thermal comfort controls based on project type, space function and occupant needs. Thermostat, ceiling fan, adjustable indoor floor diffusers, operable windows are some comfort controls.
- (4) Select thermal Comfort Standard. Select the thermal comfort standard that is suited for the project.
- (5) Commissioning as per design is a crucial step so that the building performs as designed. Performance monitoring for both comfort and energy use is necessary for high performance buildings. Occupant comfort also depends on operation of the building as designed e.g., if a building is designed to benefit from natural ventilation during a certain time of the day by opening the windows, the occupant should have knowledge about it (Fig. 6).

Fig. 6 Convective wall for ventilation.

TERI Bangalore, Office Building

TERI Bangalore – office building is a unique one with solar energy and daylighting used generously to reduce energy consumption. The entrance to the building is on the northern side. The office block is towards the east, and the guesthouse is on the quieter, western end. Traversing the office space you encounter a series of naturally ventilated, and comfortable working spaces, brightly lit using daylight. Energy expense is saved by reducing the energy consumed in lighting. Instead of relying completely on artificial lighting, skylights have been built to allow natural daylight in. Intelligent systems switch between conventional lighting systems and daylighting to maintain visual comfort.

- Behind the building runs a foul-smelling open drain. This was a challenge but an innovative solution was evolved – the use of convection currents to divert smelly air away from the building. This was done by constructing an absorptive double wall along the periphery, with the outer wall made of black stone. When the sun heats the air in the 200 mm gap between the walls, the air rises, setting up a circulation there as well as in the building behind it. Small vents at the top of the wall serve as an outlet for this heated air, providing natural ventilation within the building and also insulation from the sun's heat.
- TERI's building has exploited the sun as an abundant source of sustainable energy. Solar water-heating systems provide hot water to all utilities.

This building is a remarkable exhibition of sensitivity to the environment, sustainable energy use, and modern design, a combination worthy of duplication in today's world where resources are limited. However, the occupants need to be sensitised on how the building functions to give comfort. If the vents for air movement are closed, the ventilation system won't function. Similarly, the daylight shelves and glazing systems need be maintained and cleaned for daylight access. Glare control also had to be put in place to avoid discomfort glare during specific times of the day.

Daylight, Electric Light and Circadian Rhythm (Delos Living LLC, 2016)

Access to daylight has great human health benefits as it reinforces our circadian rhythm. Daylight in buildings helps save on electricity consumption in lighting systems. Glare from daylight should be avoided. Daylight can be designed for and measured using tools. Spatial daylight autonomy (percentage of floor space where a minimum, light level e.g., 250–300 lux) can be met completely for some proportion (say 70% of regular operating hours by natural light) and annual sunlight exposure (ASE: Percentage of space in which light level from direct sun alone exceeds a pre-defined threshold (such as 1000 lux) for some quantity of hours (such as 250 h in a year)). These two indices can be used to ensure that a space is adequately daylight and yet there is limit on inappropriately high levels of sunlight. As per WELL Building Standard V1.0 spatial daylight autonomy (SDA 300, 50%) is required to be achieved for at least 55% of regularly occupied space. In other words, at least 55% of space receives at least 300 lux of sunlight for at least 50% of operating hours each year. LEED v4 provides incremental thresholds for 55%–90% of spaces achieving SDA (300, 50%). ASE (1000, 250) which means that no more than 10% of the area can receive more than 1000 lux for 250 h each year is common for both the rating systems. The SDA and ASE can be analysed using computer simulation tools and followed up by daylight measurements on site.

Good daylighting design has to follow the steps as below:

- (1) Set the design goals. Daylight design goals should be set for the project. The spaces should be organized in a way to have maximum daylight in regularly occupied spaces that benefit from daylight e.g., workstations in offices, patient room in healthcare facilities benefit from daylight and should be placed in periphery of buildings. Spaces such as auditoriums, audio-visual rooms etc that do not benefit from daylight integration could be placed in areas that do not have daylight access.
- (2) Building design and massing. Building siting and massing has great impact on daylighting. Thinner building footprint has better daylight integration possibility. Orientation and shading are two key strategies for daylighting. Consider incorporating both vertical fenestrations in form of windows/clerestoreys or glazing systems and horizontal systems such as atria/skylights for daylight integration. Courtyard spaces light wells are techniques for daylighting in deep office spaces.
- (3) Control glare through shading and controls. Daylight can only be effectively used, if it is glare free. Glare control devices are in form of window blinds, shades, curtains, moveable exterior louvers, screens. Typically occupant should be able to control use of glare control devices (Fig. 7).

Take the example of LEED Platinum YKK building in Tokyo Japan

The YKK building, situated in the thick urban setting of Chiyoda-ku Tokyo, is a LEED Platinum Core and Shell building. The façade is very interesting and aesthetically pleasing. However an intelligent façade design ensures favourable daylighting without glare. A sun screen provides sun protection but allows daylight to penetrate through clear double glazing. Specially designed “bottom up” blinds can be pulled down in case of glare, while also allowing daylight to filter.

Overall lighting comfort is important to ensure that a building functions to maintain uniform lighting.

Good electric lighting design is an important aspect of high performance building. Maintaining lighting standards for illumination with minimum energy expenditure with adequate controls help save energy but enables visual comfort.

In addition to providing visual comfort and ability to see objects, Light drives the circadian system that regulates physiological rhythms throughout the body's tissues and organs affecting hormone levels and the sleep-wake cycle. Circadian rhythms is largely regulated by light which the body responds to in a way facilitated by intrinsically photosensitive retinal ganglion cells (ipRGCs): the eyes' non-image forming photoreceptors. Through ipRGCs, high frequency and high intensity light promote alertness, while the absence of this stimulus signals the body to prepare for sleep. The biological effects of light on humans can be measured in Equivalent Melanopic Lux (EML), a proposed alternate metric by the WELL Building standard that is weighted to the ipRGCs instead of to the cones, which is the case with traditional illumination level measured by Lux level.

Thus occupant visual comfort is a combination of illumination level to suit function of the space, lack of glare, ability to see objects in true color, light to boost circadian rhythm, and other parameters such as brightness, contrast etc. All these should be achievable at minimum energy expenditure by switching to efficient sources such as light emitting diodes etc and a mix of controls. Choice of luminaires attributes significantly to proper lighting distribution and glare control.

Fig. 7 Cross section of YKK building, Tokyo demonstrating innovative daylight strategies.

Indoor Air Quality

Incidence of fatigue, dizziness and loss of productivity is a common phenomenon in many offices not designed to maintain desirable air quality. Emissions from materials/furniture and furnishings including finishes, paints, varnishes, adhesive and sealants etc in form of Volatile organic compounds (VOCs) are one of the main causes of Indoor air pollution. Other common causes of bad IAQ are increased CO₂ levels due to poor ventilation, particulate matter, tobacco smoke or pollutants such as carbon monoxide (CO), ozone. The outdoor air quality in vicinity of spaces have a direct co-relation with indoor air quality. Bad indoor air has significant impact on health and wellness of occupants of a space. VOCs, combustion by-products such as CO, air borne particulate matter are known to trigger nausea, headaches, asthma, respiratory irritation and allergies. Acceptable limits of pollutants as per international standards for some common indoor air pollutants are:

- Formaldehyde levels less than 27 ppb.
- Total volatile organic compounds less than 500 µg/m³.
- Carbon monoxide less than 9 ppm.
- PM_{2.5} less than 15 µg/m³.
- PM₁₀ less than 50 µg/m³.
- Ozone less than 51 ppb.
- Radon less than 4 pCi/L in the lowest occupied level of the project.
- CO₂ less than 800 ppm.

Further, smoking should be completely banned indoors. The average life expectancy of a smoker is 10 years less than a non-smoker. In addition to nicotine, cigarettes contain about 600 ingredients that form over 7000 compounds when burned, of which at least 69 are known to be carcinogenic. Second hand smoke exposes non-smokers to the same toxins, increasing the number of people subject to health risks from smoking.

A high performance can devise several strategies to have controlled IAQ. Some options are as follows:

- Demand controlled ventilation to maintain level CO₂ level within limit. Design of ventilation system in a mechanically or naturally ventilated building should be done using Ashrae 62.1 standard, latest version or international equivalent.
- Filtration of outdoor air as well as return air in air handling units to remove particulate matter of multiple sizes. Finding out sources of contamination is another critical aspect of good IAQ design. Building nearer to traffic emission sources need to be more cognizant of NO_x CO, ozone as possible pollutants in addition to particulate matter and Volatile Organic Compounds (VOCs). The particulate matter concentration and its fineness distribution is also key to choice of filtration systems. For example installation of very high efficiency filters such as MERV 13 in isolation many not be appropriate in regions with high levels of coarse particles. Multi level filtration is necessary in such situation where a pre-filtration is applied to remove coarse particle followed by higher efficiency filters. Activated carbon filters are also recommended to remove VOCs. In buildings with air-conditioning, it is recommended to employ ultraviolet lamps (using a wavelength of 254 nm so as not to generate ozone) on the cooling coils and drain pans of the mechanical system supplies, to prevent mold growth. The filter guide to particulate matter is illustrated in figure below (Fig. 8):
- Select furniture, finishes, paints, adhesives etc with no VOCs. Testing and certification to international standards is very important. Please refer to LEEDv 4.1 and WELL Building Standard for international standards that should be referred.
- *Use of plants indoors for better air quality:* Certain common indoor plants (Areca Palm, Rubber plant etc.) provides a natural way of removing toxic agents such as benzene, formaldehyde and trichloroethylene from the air, helping neutralize the effects of sick building syndrome. However, it may be noted that indoor plants can hardly be beneficial for controlling particulate matter (PM 2.5 and 10) and need for filtration media is essential for removing particulates (Figs. 9 and 10).

Fig. 8 Filtration efficiency.

Case Study: Paharpur Business Centre (PBC), New Delhi

Paharpur Business Centre (PBC), (see "Relevant Website section") is India's first retrofit USGBC LEED Platinum certified green office building in heart of New, Delhi India is located in one of the most polluted places in Delhi; It is currently operating at an average annual electricity consumption of $<17 \text{ Wh/m}^2/\text{h}$. The $\sim 5000 \text{ m}^2$ building is filled with >7000 natural green plants grown, both in special soil and hydroponics and grows its own fresh air. The building, located in an area with high levels of outdoor air pollution has a very good air quality, thanks to extensive air filtration strategies deployed and use of plants for air quality enhancements. PBC has a hybrid air filtration system that includes mechanical equipments and air-filtration plants, grown in Hydroponics. It has a pre-treatment air plant and the building is kept at a positive pressure in order to avoid ingress of outside polluted air.

This unit consists of various components including a Heat Exchanger to pre cool the air without adding humidity to it. The air further passes through Microvee and HEPA filters. Electrostatic filter is used to remove particles from the air by using highly charged electrodes that ionizes the air. In air purification system, activated carbon filters are used in conjunction with HEPA filters to trap allergens and impurities like ozone, dust, lint, mold spores, smoke, benzene and other VOCs. This cooled air goes to greenhouse, which has patented planters with special plants, grown in hydroponics to reduce bacteria and fungus, VOC's and CO_2 in the air. The building is kept at a positive pressure in order to avoid ingress of outside polluted air.

Indoor Air Quality at PBC conforms to:

Temperature: $22 \pm 1^\circ\text{C}$ in winters and $25 \pm 1^\circ\text{C}$ in summers.

RH $70\% \pm 10\%$

PM $1 < 11 \mu\text{g/m}^3$

PM $2.5 < \sim 15 \mu\text{g/m}^3$

PM $10 < 50 \mu\text{g/m}^3$

Sox, $< 40 \mu\text{g/m}^3$

Nox $< 40 \mu\text{g/m}^3$

Ozone $< 50 \text{ ppb}$

TVOC's $< 500 \mu\text{g/m}^3$

$\text{CO}_2 < 350 \text{ ppm}$ above ambient

$\text{CO} < 2 \text{ ppm}$

$\text{CH}_2\text{O} < 30 \mu\text{g/m}^3$

Microbial Count $< 50 \text{ CFU/m}^3$

Compared to other buildings, there is a reduction at PBC, in the incidence of

- Eye Irritation by 52%
- Respiratory Symptoms by 34%
- Headaches by 24%
- Lung Impairment and Asthma by 12%.

Fig. 10 Greenhouse in Paharpur business centre.

While design interventions can significantly influence quality of indoor air, it is equally important to have occupant knowledge of the systems and ability to monitor and maintain. Filtration needs to be regularly checked, filters need to be cleaned or replaced, as needed. Outdoor air should be monitored and controlled as per demand of indoor spaces. It is a very regular finding in many offices, that the outdoor air system is often shut down to reduce energy consumption. This can have serious health impact and lead to sick building syndrome. It is advisable to have regular monitoring and display of common indoor air pollutants to enable taking corrective steps.

Global green building rating systems such as LEED (Leadership in Energy and Environmental Building Design) provides adequate guidance to design and maintenance of high performance buildings.

Conclusions

A High performance building, thus evolves through a careful design process and has to be maintained at high level of performance through occupant knowledge of systems, monitoring of performance parameters and by taking adequate corrective actions, if it fails to perform. Such buildings also, can be designed and maintained to improve on performance over time, by taking suitable retrofit actions. High performance buildings need to be carefully designed by setting performance goals that could be set at a whole building level or at component or system level. Performance goals are varied that can comprise energy consumption per unit area or per occupant, thermal, visual or acoustic comfort provided and maintained, indoor air quality maintained etc. Achievement of high performance is not only a design goal but a long term goal over life of building. Thus operation and maintenance plays a significant role to ensure this. LEED rating system provides guidance on designing and maintaining high performance buildings.

What is Lime?

Lime is a dehydrated and calcined mineral comprised of Calcium and Magnesium oxides and hydroxides. In the raw form, it is extracted from 'Limestone' (CaCO_3), which is a naturally occurring sedimentary rock and is found in abundance throughout the world. Geologically, limestones are 100–500 million years old and were formed out of compressed calcareous sea remains. Today, it is mined from quarries and is pulverised before being sent to the kilns to be burnt at temperatures ranging from 700 to 900°C to remove the impurities, moisture and excess carbonic content in the form CO_2 . The highly hydrophilic and caustic burnt product, Calcium Oxide (CaO), when mixed with water undergoes an exothermic reaction to yield an alkaline mixture known as 'slaked lime' – Ca(OH)_2 . Slaked lime is adhesive in nature and is generally mixed with multiple aggregates to prepare plasters or mortars, which, with prolonged exposure to ambient air and the sun, undergo carbonation to re-establish itself in its carbonate form. This process, as indicated in Fig. 1, holds true when the raw limestone is pure in nature, i.e., it contains more than 95% of CaCO_3 . The slaked lime yielded after processing pure limestone is called as 'non-hydraulic lime'.

Limestone, in abundance is not found in its pure form. The impure limestone generally contain oxides of Silica, Aluminium, and Iron. However, depending on the geological history of the land, these compounds largely vary, and so does the adhesive nature of the plasters/mortars formed with this 'hydraulic lime'. Vicat, in his early works in the 19th century quoted on the 'Cementation Index' of hydraulic and non-hydraulic limes, which governs the hydraulicity of any lime substrate (Vicat, 2014). Depending on the concentration of the active clay component (impurity), limes are characterised as (Non Hydraulic Lime-n) NHL₂, NHL_{3.5}, NHL₅ etc.; the numbers in suffix govern multiple physical characters of the substrate. For example: the porosity and resultant water permeability of limes decreases as the number in suffix increases; i.e., pure NHL has the highest water permeability, while NHL₅ has the lowest.

Physical Properties

Rangarajan comments on the porous nature of lime, which allows the façade to breathe and remediate the problem of moulds. In addition to its hygroscopic characteristics, lime has a lower embodied energy in comparison to the popular building fabrics like cement (Reddy and Jagadish, 2003). Edwards, in his thesis on 'Properties of hydraulic and non-hydraulic limes for use in construction' has performed experiments to bring out the physical properties of limes. He used Fen-X lime mortar blocks made as per the British standards and cured them under controlled environments (Edwards, 2005). The Table 1 compares the compressive strength of air and water cured Fen-X lime mortar mixed with coarse sand in the lime:sand ratios of 1:1, 1:2, and 1:3 for 1, 2, 4, and 8 weeks of duration.

Fen-X, being a natural hydraulic lime, had the capacity to cure under water too (Constructo, n.d.). It can be seen from the compressive strength measurements, the curing was quicker in air for 1:1 mixture of sand and lime for a prolonged period. However, the 1:2 and 1:3 mixtures for the 'water' case were found to be more durable. Had the substrate been non-hydraulic, the

Fig. 1 The lime cycle.

Table 1 Compressive strength of hydraulic lime mortar blocks, mixed with coarse sand in ratios 1:1, 1:2, 1:3, and cured in air and water for 1, 2, 4, and 8 weeks

Weeks	Compressive Strength (N/mm ²)					
	Air Cured (Lime:Sand)			Water Cured (Lime:Sand)

8	6.04	2.19	1.17	4.95	3.18	2.33

Note: Edwards, A.J., 2005. Properties of hydraulic and non-hydraulic limes for use in construction. Doctoral Dissertation, Edinburgh Napier University.

**Fig. 2** Variation of compressive strength with curing temperature for 1:1, 1:2, and 1:3 ratio mortars of lime and sand. Reproduced from Edwards, A.J., 2005. Properties of hydraulic and non-hydraulic limes for use in construction. Doctoral Dissertation, Edinburgh Napier University.

mortar under water would not have hardened at all. In addition to the ambient state, the curing temperature of air also plays a major role in the hardening of the lime. **Fig. 2** below, based on the tabulations by Edwards, shows the variation of compressive strength of lime mortar blocks of 1:1, 1:2, and 1:3 ratio of lime and sand, cured at temperatures ranging from -14 to 120°C (Edwards, 2005). The blocks with 1:1 ratio of sand and lime were found to be the strongest when cured at 55°C , while sub-zero atmospheric temperatures yielded low strength. Therefore, a lime structure made out of same materials in northern Europe will be weaker than one made in central Africa.

The ability to absorb water is one of the most unique characteristics of lime mortar and plaster. The porous nature of solidified lime contributes to the reduction of ambient humidity. Raw limestone has a porosity percentage varying between 2% and 8%, while the pore size ranges between 10 and 100 nm (Atlas, 1981). The extent of porosity of the final hardened product depends on the lime sintering temperature. High temperature leads to emission of CO_2 and consequently leads to shrinkage of the crystal structure. This causes the creation of new interstitial gaps and widening of the existent ones to serve as ideal spots for water molecules to be adsorbed. The porosity of a regular air dried lime mortar is 30% with a 14% water absorption - both of these percentages decrease with the fraction of sand (Edwards, 2005).

Lime in Daily Life

The inception of usage of lime by humans happened about 10,000 years ago (Carran *et al.*, 2012). Its glimpses can be found throughout the history - be it the 7000 year old remains of Jordan valley, the 3000 year old Harappan colonies, or the 2000 year old roman Pantheon, all incorporate lime in one or the other form (Ellis, 2001; Rao, 1979; Muench, 2017). **Fig. 3** shows the white lime plastered walls of the Padmanabhapuram palace in Tamil Nadu, India. The palace was constructed around 1601 CE and includes multiple independent structures for different functions - the centre of the complex includes a four-storeyed mansion for the royal residence.

As discussed in the section above, the ripening of lime mortar and plaster is optimised at relatively high ambient temperatures; its hygroscopic nature allows the absorption of excessive moisture, while the white colour adds to the albedo to regulate the

Fig. 3 Lime plastered walls under traditional tiled roofing in the Padmanabhapuram palace, Tamil Nadu.

Fig. 4 Usage of lime across industries. Reproduced from Atlas, S., 1981. Process Engineering of Metals and Ceramics. Characterisation of Limestone and Lime. Düsseldorf, Germany: Verlag Stahleisen MBH. 28. Available at: http://www.ltv.ovgu.de/ltv_media/Downloads/Lehre/Vorlesungen/Process+Engineering+of+Metals+and+Ceramics/Chapter+5+Characterisation+of+limestone+and+lime.pdf.

indoor temperatures. Free lime present in the building plaster absorbs low amounts of CO₂ for a prolonged period, and helps keep the indoor environment quality in check (Anon2). The possibility of producing lime at a small scale, and in a varied proportion with multiple aggregates makes it a great binder. Because of being partly water soluble due to the presence of compounds like gypsum, the remediation of cracks is easier in lime – water carries the soluble molecules from healthier portions of the plaster into the cracks and crevices to ultimately dry and solidify into a new chunk of plaster (Rangarajan). These and more are the reasons why lime has been widely used across civilisations and ages for constructing particular building elements or the entire structures (Kapoor and Gujral, 2017).

In the present scenario, buildings utilise only 10% of the total lime used by humans. Other industries such as steel, and water purification utilise a major portion of it as shown in the figure below (Fig. 4).

Buildings in Lime

Buildings consume about 40% of the total global energy (Pérez-Lombard *et al.*, 2008). The tropical climates incur huge cooling loads and have the opportunity of incorporating passive design strategies for a lower carbon footprint. The applicability of lime as a building fabric is highest in the ‘warm and humid’ climate zone defined as per the Indian ECBC (Energy Conservation Building Code) and NBC (National Building Code) – in these climates, the white exteriors reflect light and reduce façade temperatures, while the porous nature moderates the indoor relative humidity (Energy Conservation Building Code, 2017; National Building Code of India, 2005). This helps reduce the need for energy intensive HVAC systems and ultimately results in enhanced sustainability. In order to understand the thermal behavior of buildings incorporating lime plaster and mortar, two occupied buildings – Language Lab (LL) and Mukuduvidu Residence (MR), located in the international township of Auroville, Tamil Nadu, were studied for air/surface temperatures and relative humidity through permanent data loggers and hand-held instruments for the hottest portion of the year.

Fig. 5 Buildings under study: (a) North façade of LL. (b) Central courtyard in LL. (c) North Façade of MR. (d) Indoor view under the vault. (e) Window detail in the dome.

Buildings Under Study

Language Lab (shown in [Fig. 5\(a\)](#)) is a distinctive centre known for teaching languages through its guided study programmes and practicing the Tomatis therapy for cognitive development and psychological wellbeing ([Anon3](#)). The building had a constructed area of 930 m² per floor and came under the category of ‘educational buildings’ as per the Indian NBC. The function of the building required the indoors to be moderated from the ambient heat and provide a mellow backdrop for the therapy rooms. During peak hours of group classes, there were around 50 occupants in the building. All the interior surfaces of the structure were plastered in fine *kadukkai* infused lime on the inside and a coarse lime on the exterior. The slabs of the two floors, including the roof, were made up of reinforced concrete – the floors were covered in polished stone, while the rooftop surface was plastered in white lime. The 27 m², pebble filled central courtyard (as shown in [Fig. 5\(b\)](#)) provided daylight to the indoors while helping maintain a constant wind circulation. The building was occupied and functional during the measurement period, however, multiple sustainability-enhancing elements like cooling towers and solar water heaters were still under construction.

Mukuduvidu (shown in [Fig. 5\(c\)](#)) was a residential building as per the Indian NBC and housed 2–3 occupants throughout the year. The building extensively utilized lime as a mortar and plaster. However, unlike conventional modern lime structures, it used domes and vaults as the architectural form ([Fig. 5\(d and e\)](#)). The two identical domes were 4.8 m in diameter and had an external surface area of 36 m² each, while the lime plastered surface above the vault had a surface area of ~90 m². The domes and the vault is made entirely out of country fired bricks and lime mortar, while the structure of the building also utilized granite slabs and exposed concrete. Located amidst the thickets of bamboo, deciduous trees, and a naturally maintained pond, the building was designed to moderate the indoor thermal environment. It incorporated the tandem of structural and functional sustainability by using optimal size and construction strategies ([Doctor-Pingel et al., 2014](#)). The study for this case focused on contrasting the thermal properties of domes versus vaults made in lime. Interior and exterior surface temperatures for the two domes and vault, as well as air temperature in the spaces under the domes and vault were monitored.

[Fig. 6\(a and b\)](#) show the plan of the buildings with the zones under study. The windows/voids in the buildings, highlighted in yellow allowed efficient air ingress and kept the indoors cool. During the period of study of LL (June 2018) and MR (May 2014), the most prominent wind direction was due South-West.

Local Additives to Lime

LL and MR used lime mortar and plaster made with a fermented mixture of crushed *Terminalia chebula* or ‘Kadukkai’ seeds and jaggery water throughout the building. The mixture of these two components made the plaster water resistant and added

Fig. 6 (a) Plan of LL. (b) MR with the zones under study highlighted in red. The open courtyard in LL is highlighted in green; the blue arrows indicate the prominent seasonal wind direction while the openings/windows are highlighted in yellow.

a beige tinge to the natural colour, while preserving the elemental cool characteristics of lime. Before being mixed in a ratio of 9:10 (Kadukkai: jaggery) with 300–400 litres of unchlorinated water, the Kadukkai seeds were ground coarsely. The Kadukkai, jaggery and water mixture was fermented for two days before being mixed with lime. This mixture was allowed to rest for two weeks in sealed containers. Thereafter, the mixture was used to prepare the plaster with one part lime per three parts sand. The plaster was applied in two coats – the first, coarse coat was allowed to dry for a day before the application of the final coat with a higher amount of fermented water mixture for a smoother finish. The occupants preferred the beige tone of Kadukkai infused lime in LL, while the occupants preferred white indoors and painted the surfaces in white lime in MR. Emayan, in his work on compressive strength of lime mortar with jaggery and Kadukkai admixtures found out that the compressive strength of lime mortar prepared as per the aforementioned method yielded a compressive strength of 1–2.24 N/mm² for a two-week curing period (Emayan and Rahuman, 2015). In addition to this admixture, traditional Indian construction practices have been using edibles like curd, gram, and plant based substrates as additives in lime mortar since centuries, as can be seen in Table 2 (Thirumalini and Sekar, 2013). Attempts have also been made to use potato starch to improve the viscosity and workability of lime based mortars (Izaguirre *et al.*, 2010).

Instrumentation and Data Logging

In order to study the indoor parameters of the two buildings, research questions concerning the behavior of various building elements were formulated and strategic logger placement positions were identified. Fig. 7 shows the types of loggers and hand-held equipment used for the analysis as per the following site-specific research questions:

Case 1: LL

- (1) What were the internal and external surface temperatures of the East, West, North, and South facades throughout the day?
- (2) What was the difference between the roof surface and the ceiling surface temperatures for the hottest hours of the day?
- (3) How did the indoor air temperatures and relative humidity vary across various occupied zones?

Case 2: MR

- (1) What were the internal and external surface temperatures for the two domes and vault throughout the day?
- (2) How did the surface temperature vary with height for the domes?
- (3) How did the indoor air temperature and relative humidity vary for the occupied spaces under the domes and vault?

The measurements across the two buildings involved long-term logging with the help of HOBO loggers as shown in Fig. 7(a). Three kinds of loggers (types B, C and D) were used as per the requirements. Logger B (U12-013) measured air temperature and RH through

Table 2 Usage of traditional organic additives in lime mortar in India

Additives	Purpose
Curd	Finishing

Plant Gum	Retarding
Raw Sugar	Bonding
Straw	Crack Prevention
Glue	Bonding
Jaggery	Hardening

Note: Thirumalini, P., Sekar, S.K., 2013. Review on herbs used as admixture in lime mortar used in ancient structures. Indian Journal of Applied Research 3 (8), 295–298.

Fig. 7 Instrumentation equipment: (a) Type B, C, and D long-term HOBO loggers. (b) Hand-held Fluke 561 IR Thermometer and EXTECH HT30 Globe Thermometer.

inbuilt sensors and had the provision of two external sensor connections, which in our case were used for surface temperature measurement. Logger C (U12-006) did not have any in-built sensor and was used to measure surface temperature through its four external channels, whereas Logger D (UX100-011) was used to measure air temperature and RH through the built in sensors.

Hand-held equipment, as shown in Fig. 7(b), were used to gather instantaneous readings of the same parameters as measured by the long-term loggers. Instantaneous air and surface temperatures with RH were measured on a sporadic basis and compared against the long-term readings. A comparison between the typical hand-held and long-term readings for LL is given in Appendix A.

The two buildings were placed with multiple type B, C, and D loggers at strategic locations to measure the surface and air temperatures. The locations of logger placement, with the photos of the loggers on site are shown in Figs. 8 and 9.

The data from these loggers was collected after a monitoring of two weeks (6 June 2018–22 June 2018) for LL, and one month (1 May 2014–31 May 2014) for MR as a part of two independent studies. During the monitoring period, the loggers were inspected for loose connections, battery status, and quality of readings. For analysis, the readings were hourly averaged and compared on a case-by-case basis.

Results and Discussion

Language Lab (LL)

The surface temperature sensors installed on the four leading lime plastered walls logged the internal and external surface temperature readings. As shown in Fig. 10(a) - the walls were 640 mm thick and were made out of fired bricks with a lime mortar and Kadukkai-lime plaster on either sides. The exterior side had a coarse plaster finish (35 mm thick) while the interior side had a finer plaster layer (25 mm thick). The wall included a 115 mm air cavity to increase the thermal resistance.

The temperatures across these two surfaces varied with the sun's position throughout the day – the gradual incidence of sun was evident in the early hours on the exterior temperatures of the eastern façade, while as the noon passed, the temperature plateaued

Fig. 9 Loggers placed in LL (B1, B2, B3, B4 and C1) and MR (B5, B6, B7 and C2).

Fig. 10 Cross section of: (a) wall. (b) roof in Language Lab.

Fig. 11 Hourly averaged surface temperatures for the four leading lime plastered facades.

until the late evening. This was when the sun struck the western façade and elevated its exterior temperature to 1° lesser than the exterior of the eastern façade (41.62°C). As shown in [Fig. 11](#), the west wall was found to be warmer than the east wall in terms of peak temperature. This was because the low ambient temperatures during the night and early morning allowed the east wall to cool down to as low as 27.8°C , which required a higher amount of heat to be brought to an elevated temperature. However, the warmer ambient air and diffused component of solar radiation brought the west wall in the range of $35\text{--}37^\circ\text{C}$ during the late morning hours, even before direct solar radiation struck it. The highest exterior surface temperature of the north and south walls remained at 36.4°C and 37.0°C respectively as at no point of time did the direct sunlight fall on the wall. The indoors surface temperatures across each of the walls were moderated in the range of $30.5\text{--}33.3^\circ\text{C}$ with diurnal fluctuations of 1.2° , 1.5° , 2.8° , and 0.6°C for East, West, North, and South walls respectively. The thermal time lag – time difference between the outdoor and indoor maximum temperatures – was found to be 6 h for the east and south walls, while the west and north walls had a minimal time lag

Fig. 12 Hourly averaged surface temperature for the lime plastered roof.

Fig. 13 Hourly averaged air temperatures for occupied rooms and the central courtyard.

of 1 h each. The east and south zones under study were unoccupied for most of the time during the period of study and did not have their windows open for cross ventilation to influence the indoor temperatures. While the western zone experienced constant occupancy with open windows and the operation of a ceiling fan, in addition to the northern zone being ventilated by two continuously open windows – this enhanced the convective exchange with the ambient air and resulted in temperatures higher than the interior surfaces on the east and south.

The roof, as shown in Fig. 10(b) was made out of reinforced concrete (150 mm), a layer of brick bat lime concrete (50 mm) and lime plaster on either sides (similar thickness to wall). Fig. 12 shows the hourly averaged surface temperatures for the internal and external surfaces of the roof. The white lime plastered exterior surface went as high as 43.5°C during the period of study while the internal ceiling surface was moderated at 33.1°C for the hottest hour, creating a thermal difference of 10.4°C. The thermal time lag between the exterior and interior was of 2 h – which is low, considering the high thermal mass and reflectivity of the white lime plaster. The possible explanation for this can be that the ceiling surface under study was exposed to the courtyard zone, which experienced conditions similar to the outdoor environment. The air temperature of courtyard would have affected the ceiling temperature and overshadowed the insulating characteristics of the roof.

Fig. 13 shows the hourly averaged air temperature and relative humidity trends for the four occupied zones and the courtyard. The parameters across the courtyard were closest to the outdoor parameters for it was exposed to the ambience and was open from all four directions at the top. The northern part of courtyard was closest to the fenestration, thus experienced a higher diurnal variation of 7.7°C and 27.9% RH in comparison to 5.6°C and 21.1% RH of the southern part. The studied rooms were warmer and less humid than the courtyard during the non-daylight hours, while the opposite was true during the daylight hours. The air temperature of the rooms was moderated in the range of 30.3–34.0°C, with the northern room being the warmest for the aforementioned reason concerning surface temperatures. There was a fluctuation of 1.7°, 2.3°, 3.7° and 2.8°C for the east, west, north and south rooms respectively, while the RH varied with 9.2%, 11.2%, 15.5%, and 10.7% for the respective rooms.

Mukuduvidu Residence (MR)

The two domes and vault studied for this case, as shown in Fig. 14, were dominantly made out of kiln fired brick and lime. The first dome had a glass cover (open at the sides) at the top to restrict rain, while the second dome had a wind-operated mechanical ventilator. Additionally, both the domes had openable windows as indicated in Fig. 6(b). The vault had mosquito-mesh covered openings right under the arches on either sides to allow natural ventilation. The reflective white exterior surfaces of the domes and the vault were studied for surface temperatures at various heights and the thermal trends are shown in Fig. 15.

The three heights H1, H2, and H3 correspond to 84, 271, and 317 cm from the floor level for the case of domes. The interior and exterior surface temperatures in the two domes increased with the height. However, the magnitude of peak temperatures varied considerably. For the hottest hour of the day, the exterior surface temperatures for dome 1 and 2 at the

Fig. 14 Section of the two domes and the vault in Mukuduvidu.

Fig. 15 Hourly averaged interior and exterior surface temperatures for the two domes and vault.

Fig. 16 Hourly averaged air temperature and relative humidity for the zones under the domes and vault.

three height levels were 38.2°, 38.7°, 47.3°C and 39.6°, 43.3°, 48.7°C respectively, while the interior surface temperatures were at 31.8°, 32.4°, 33.7°C and 31.5°, 32.8°, 34.0°C respectively. There existed a thermal time lag of 6 and 5 h at the highest levels for domes 1 and 2 respectively. The exterior surface temperature across the vault was lower than that of the domes by 5.3°C, while the vault ceiling temperature remained between 30.7 and 31.8°C throughout the day with a minimal thermal time lag of 2 h.

Fig. 16 shows the variation of hourly averaged air temperature and RH of the zones under the two domes and the vault. The outdoor air temperature and RH varied in the range of 26.6–34.7°C and 57.3%–88.7%. The highest temperature across the zones

under domes was 32.1°C and 32.2°C, with the lower limits being 30.0°C and 29.6°C respectively. The vault zone had a better ventilation and resulted in a temperature range of 29.1–31.8°C. The efficient ventilation for the case of vault was also reflected in the time lag for air temperatures. The air in zone under the domes had a time lag of 6 and 3 h with respect to the ambient air, while the vault had a time lag of 2 h. The air in the domes was at lower RH levels in comparison to the domes. For the coldest hour of the day, the zones under the domes had 73.7% and 76.3% RH, in comparison to 79.8% RH of the vault zone.

Conclusion

This article discussed the merits of using lime as a building fabric, its physical properties as per existing literature and its performance in moderating temperatures across built structures. Some of the benefits of using lime are:

- Abundant availability throughout the globe.
- Simplistic processes (burning, slaking, & carbonation) and involvement of non-toxic chemicals.
- Recyclability.
- Comparable physical properties to cement-based fabrics.
- Freedom of choice of aggregates.
- Ability to cure under water (for the case of hydraulic lime).
- Progressive increase in strength over time.
- Porosity of the cured surface (helps regulate humidity).
- Easy remediation of cracks and defects in comparison to conventional building fabrics.
- Possibility of mixing various natural substrates for enhanced properties.
- Moderate to high optimum curing temperatures (adept for warmer tropical regions).
- Natural white colour with high reflectivity.
- Possibility of downscaling the production as per need, etc.

In addition to the aforementioned points, use of lime as a building fabric proves to be thermally optimal for the buildings in the warm-humid climatic zones. The study of thermal parameters across the various 'Kadukkai'-lime plastered surfaces and occupied zones for Language Lab (LL) and Mukuduvidu Residence (MR) in the warm-humid tropical climate of Auroville, India yielded notable findings. In LL, the exterior temperatures for the east and west façades were higher than the north and south façades by 10.7%, while the internal surfaces of the façades, at an average, were cooler than the exterior surfaces by 16.8%. The air temperatures of the directional occupied zones were found to be cooler than the naturally ventilated courtyard by 4.2% during the hottest hour of the day – however, due to the lack of outdoor temperature readings, one cannot make a conclusive statement about the air temperature in this case. For MR, the exterior surface of the vault was cooler than the domes by 10.8%, while the interiors of the vault were cooler by 6.5%. The highest point of exterior surface temperature measurement (H1) was warmer than the lowest point (H3) by 18.7% for the two domes. The air temperatures in the zone under the vault was cooler than the zones under the domes by 1.3% for the hottest hour of the day, while the same was cooler by 3.1% for the coldest hour of the day. The domes performed better in terms of thermal time lag, while vault was able to maintain a higher temperature difference. The domes were also able to reduce the relative humidity levels by 7.3% in comparison to the vault. The extent of ventilation for the two building forms played a major role in defining the thermal variables in the respective zones.

Despite the existent research, there exists a wide scope of research on a wide variety of limes and their usage in structures throughout the world. The abundant knowledge must be documented from the traditional artisans, who have been meticulously perfecting the art of building in lime since generations to identify the best-possible solutions to the modern building needs and support the sustainable building fabric called lime.

Acknowledgement

We thank Tapas and Mita, from the Language Lab for facilitating a smooth study. We also thank the CBERD project team from Auroville Centre for Scientific Research and Studio Naqshbandi for the study of Mukuduvidu Residence.

For Mukuduvidu Residence: the U.S. Department of Energy (DOE) and the Department of Science and Technology (DST), Government of India (GOI) provided joint funding for work under the U.S.–India Partnership to Advance Clean Energy Research (PACE-R) program's "U.S.–India Joint Centre for Building Energy Research and Development" (CBERD) project. The Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Building Technology, State and Community Programmes, of the U.S. DOE under Contract No. DE-AC02-05CH11231 supported the U.S. CBERD activity. The DST, GOI, administered by Indo-U.S. Science and Technology Forum, supported the Indian CBERD activity.

Use of Steel as a Sustainable Concept

Anjan Mitra, The Appropriate Alternative, Kolkata, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Today we love to talk about Sustainability as if this one word will transform the way we think about development. Development is a pattern that replaces nature, disturbing the ecological balance with a race for rapid urbanization and in the process implementing project after project. This results in widening inequity and leaving behind a trail of devastation. Sustainability is thus a misnomer – it fluidly changes its meanings, values with a change in context and position.

Human actions can be influenced by business, politics, scientific discoveries, technological advancements or social activism. All these manmade interventions get transformed and manifested with the support of architects, designers, planners and project managers – through the act of building and creating. However, one cannot deny the inherent value of being responsible in our actions to ensure the welfare of planet earth and consider possibilities for a sustainable future. Sustainability thus becomes a concept that relies heavily on making responsible choices for planning, design and construction.

Let us begin by critically examining the pattern of development around us. In the last decade, there has been major transformations in the way the built form is conceived, designed and built, the aspirations have changed, mobility has increased many folds, different building typologies have emerged and public life, institutions have evolved or transformed to match.

We are a global civilization now and we have achieved the capability to dictate life and its associated patterns. To an extent we can even decide on the direction and future course our lives take. In this freedom and increased capacity there is a sense of supreme power and therein lie the danger. With great power comes great responsibility. And if we just take a pause at this stage and introspect, we may realize that our current approach to growth and development also foregrounds areas of grave concern.

We are growing and developing at an uncontrolled SPEED and in the process our ECOLOGY is imbalanced and threatened. We pollute our ENVIRONMENT, and our ENERGY DEMAND is continuously on the rise. Our activities destroy natural and cultural HERITAGE and create ever increasing INEQUITY in our socio-economic sectors. Most of these changes are irreversible and would likely pose major challenges for development in the future.

At this critical juncture, we, the decision makers, designers and planners need to relook at our available options and choose RESPONSIBLY for possible rectification, remedial measures and holistically sensitive approaches of our present development trajectory. As a probable direction we intend to look at Steel as an IDEA that advocates for our sustainable future.

Steel and Civilization – A Connect

With the advent of the Iron Age, mankind started developing tools and equipment. This knowledge gave humans a notion of power – for the first time they learned ways to tame and manipulate nature. From the nomadic life of being hunter-gatherers, humans became settlers. Agriculture, domestication of animals gave rise to concept of Land, Property and Settlement. Slowly an organized way of life was initiated. At the same time, there were conflicts around gaining control of prosperous land, leading to aggression. With war came weapons – the means of destruction as well as possibilities of construction. This pattern evolved and consolidated into a pattern of development where the seat of power was protected in walled cities, surrounded by trade and commercial establishments, and then agricultural land. Broadly this system was propagated through feudalism subsequent influenced patterns of human civilization (Figs. 1–3).

Around 1760, the Industrial Revolution was initiated in Great Britain when the production by hand gave way to machines for large-scale production. This embracement of technical advancement for progress brought about massive improvements in the Iron Industry and increased knowledge of production and processing.

The Industrial revolution in the late sixteenth century was successful in liberating the human civilization from mediaeval practices. The history of the modern steel industry began in 1850 and thereafter Steel has been a basic component of the world's industrial economy. Earlier, large metal structures were made of wrought iron or cast iron produced around Sheffield in Britain. During this period steel was comparatively an expensive proposition. This situation changed with the bulk production of steel, as a result of Henry Bessemer's process. Steel thus produced was cheap and readily available. With the development of iron foundries mankind managed to create improved equipment, tools and machines. Motivated by these, there was a surge in engineering. A new business class, the bourgeois entrepreneurs and financial institutions emerged – providing the required thrust for development and economic growth at an ever-increasing pace. This led to an increase in the need for raw materials – minerals, cotton, etc. to be collected at strategic centralized locations from different regions, often from areas spanning the globe. This also led to the opening up and exploration of new markets that were difficult to access. The discovery of the Steam engine and its implementation spearheaded this process of transportation. It helped in the extraction of natural ores, generation of power and developed major transportation systems like the Railways and global Shipping to facilitate transportation of bulk goods as well as mass

Fig. 1 'Celia' by Barcelona based Sculptor Jordi Díez Fernández in Steel that pays tribute to human emotions and strength.

transportation. Geographical boundaries were thus broken, and remote locations were connected. In a way, this can be seen for the genesis of the concept of Colonization itself, which creating a new sense and understanding of Economy.

The vast railway network comprised of new lines, bridges, viaducts, warehouses, terminals, stations etc. (Fig. 4). The shipping network comprised of ports, jetties, bulk material handling facilities. These new forms of buildings and infrastructure permanently altered the urban landscape. The introduction of factories and mechanization ushered in a new way of life – from feudalism to capitalism. In this new age, there were new economic concepts – capital and production became buzzwords. Trade and commerce flourished. New choices were continuously being made. The flourishing of industries such as the textile industry, building construction, shipping lines, steel production, heavy engineering, automobile industry etc. created huge job opportunities, concentrating the demand for labor and production in huge sprawling cities. This completely changed the prevalent lifestyles. The per capita income and GDP has grown considerably. More opportunities were created for people at large to spend on housing, travel, shopping or for leisure.

Socially, it transformed the way human engagement was thought of. People now talked about collaboration, mass production, and standardization. With an increased empowerment of a larger number of individuals, society started breaking free of the shackles of imperialism and started moving towards democracy. Industry, Trade and Commerce, Construction defined the modern perception of Life – created capitalists and the working class.

This also resulted in the creation of new building typologies – factories, offices, docks, warehouses, stations and terminals. They created a demand for large public spaces – the markets, plazas, auction houses, theatres, auditoriums, assembly in addition to large scale infrastructural projects – railways, bridges, aqueducts, viaducts, jetties, power plants, turbines etc. Concept of marketing the products, machineries and various brands started to emerge at this point. The great exhibition at Crystal Palace in UK showed the world an appropriate way to construct large spaces and in a very short time. A revolution in construction industry has started, with steel at the center of it all. It was at this juncture that Gustavo Eiffel created the icon of industrialization in the form of the Eiffel Tower in the Paris industrial exposition. The Statue of Liberty was also built and transported to New York (Figs. 5 and 6).

Today, there is steel in every bit of our lives. So much is its importance that the growth index of a country has increasingly been equated in terms of the per capita steel consumption.

Steel was not only restricted to the industrial sphere but found expression even in the socio-cultural sphere of human existence. Classical painters found new subjects in these newly built factories, market places, and in the exploration of the lives of common people. They explored the newly manifested dimensions of democracy, power and liberation. The languages and the images transformed (Figs. 7–9).

Slowly, skyscrapers started to dominate the urban skyline. The construction industry became heavily dependent on the steel industry. The techniques started to evolve. There was an advent of pre-engineered components, cables, tensile structures – all of which further pushed the envelope and expanded the horizons of the booming construction industry. People began to push the limits of their creative boundaries, drawing inspiration from traditional wisdom, nature and other sources at will. Connections and detailing became supremely important. Gradually, varieties of steel forms began to emerge, reaching out and working to support other building materials like, wood, stone and concrete. The interesting aspect of steel being a manmade element was that it offered immense flexibility and adaptability to meet various testing conditions and rise up to new challenges (Figs. 10 and 11).

Concerns (Existing Development Pattern)

In a deeper investigation of sustainability, the author focuses on the sustainable aspects of the manmade physical interventions and their impact on the larger ecosystem. He also raises the question of owning responsibility for such decisions and acts. These translate into a series of questions.

the Crystal Palace

Fig. 2 Drawings of The Crystal Palace, 1851 London.

Are we moving in the right direction?

Is our approach Holistic?

What kind of parameters and considerations do we use while making these choices?

Are our actions reversible, or rectifiable?

What kind of liabilities we are creating for future generations?

Fig. 3 The Crystal Palace, 1951 London.

These questions are difficult to answer, and disturbing. Yet, we must address these critically and impartially.

To understand that we must relook at the present development trends in the built environment as it is here that most of our actions are physically manifested and contested.

Urbanization

Globally there has been an advocacy for rapid urbanization. In India we are looking ahead, and we estimate that 70% of the total population will be housed in urban areas by the year 2020. At present, we have approximately 35% of the population in the urban areas. Logically an increase in urbanization would help to extend a better quality of life and create more economic opportunities in a sustainable (!) manner. Logically, this must be done through a surge in development of housing (appropriate!), create more jobs (what kind!), provide for adequate infrastructure (practical, maintainable, and upgradable), mass transport options (cheap, eco-friendly, convenient), waste management provisions (recyclable, sensitive!), communication (smart, user friendly), social infrastructure (inclusive, culture sensitive), etc. All these have to be integrated within the existing situation or through the creation of new greenfield projects. These projects look to transform inner-city areas with existing informal slums, convert high-value agriculture land in the periphery of existing urban areas, or convert wastelands, vulnerable wetlands or defunct industrial lands. All of these need to be accomplished at a great speed. This urgency triggers a chain reaction of destruction, new construction, accumulation of construction and demolition waste. We need new forms of Housing – and consequently there is a prevalence of socially isolated gated communities with multi-story blocks fragmenting the cultural fabric of the city. There is a growth of large workspaces with global footprints that occupy very large floor spaces dedicated to different time zones. With the high construction cost, these new developments in the city has been selective and has negated a large section of urban population. These groups have been forced to seek informal arrangements for housing, jobs and access to adequate infrastructure. But the development trends continue in an exclusive way. India today is thinking and planning for 100 new *smart cities* – places where urban development is inherently exclusionary.

Land and Built-up area – is a prerequisite to any kind of development. Buildable land is a scarce resource and is continuously shrinking at an alarming rate. However, major development projects are carried out through two main trajectories.

The first one is commonly known as Green field Development or New Development. Through this process, new land is built on to gradually bring marginal areas into the domain of Urban Development. Most of these lands are agricultural lands. In this process, large amounts of areas have been converted into built areas – displacing nature, local population, changing the demography and the socio-economic structure. The concept of land value has also changed from the value of production to its real-estate value. There has also been a shift in the way we build today. The structure has to be strong to support tall heights and large spans. Time has become an essential component of construction. In addition, the structure must be less environmentally disruptive as well as cost effective.

There is another kind of development, commonly called Brownfield Development. This encompasses approaches to building such as renewal, redevelopment, resettlement, rehabilitation, retrofitting or densification of existing built areas. These is an approach that is a practical solution that emerges from concerns of paucity of land for new development. However, it might also give rise to construction and demolition wastes at a massive scale.

In short, development has created an increased level of pollution, adversely impacting the quality of livable environment.

How can one tackle such a mammoth issue?

The Way Forward

To mitigate the existing destructive, environmentally damaging and inequitable trajectories of development, we are also forced to think of new patterns and approaches to development. This has to be underpinned by alternative construction techniques that are flexible,

Fig. 4 London Stations, Part of the new transport network.

recyclable, adaptable, up-scalable and versatile. These alternative construction systems should look for the versatility of materials, systems of connections, structural options and their response to other natural or manmade materials. One has to look at the wider ecosystem of construction and implementation and come up with responsible choices amongst the available alternative.

The above discussions help us to understand the interconnections of the development of human civilization to the development of science and technology for identifying the key features of the construction alternatives that we adopt.

Fig. 5 The Galleria Vittorio Emanuele II in Milan 1865–67 is an excellent example of a large public space constructed using new technology.

Fig. 6 Built using beaten copper sheets over a hollow iron structure, The Statue of Liberty with a height of 46.5 m was built by Gustave Eiffel in 1870–1880s.

The appropriate material for future development thus needs to be **RELIABLE** – it must be durable and provide adequate strength for their designed purpose, with required toughness and ductility so that the necessary profiles and forms can be designed and developed in an efficient and effective manner.

To be able to meet the myriad demands of construction and implementation needs the material must be **VERSATILE** and **ADAPTIVE** enough to be transformed into various components, shapes and forms without losing its structural integrity. The material must also be adaptive enough to be used to support and extend the capabilities of other conventional and unconventional construction materials, thereby furthering new possibilities.

REUSABILITY and **RECYCLABILITY** are the other necessary attributes that such a material and its various components must have – to minimize detrimental effects on the environment.

The earlier sections detail how steel has been an integral part of and has supported in its various forms the development of human civilization itself. At this juncture of human development, with the current technology, **STEEL** can be thought of as a unique material that can be made to behave responsibly in its various forms and be the supportive technology for guiding the human race towards development that leads to a **SUSTAINABLE FUTURE**.

The potentials of Steel as key to development of a nation is of paramount importance. Fast growing nations such as India acknowledge the fact, such as in the Annual Report 2017–18 by Ministry of Steel, Government of India. It reports that:

India is currently the world's 3rd largest producer of crude steel and is expected to become the 2nd largest producer of crude steel in the world soon.

India is also the largest producer of direct reduced iron (DRI) or sponge iron in the world. The country is also the 3rd largest consumer of finished steel (83.5 million tons in 2016) in the world, preceded by China (681.0 million tons in 2016) and the USA (91.6 million tons in 2016) The steel sector contributes to over 2% of the country's GDP and employs around 25 lakhs employed in steel/allied sectors (source: world steel association).

Steel – A Responsible Material

To understand Steel in its true perspective, it is essential to go through the following timeline.

<i>Year</i>	<i>Event type</i>	<i>Details</i>	<i>Present day country/region</i>
4000 BCE	Production	First evidence of use of iron.	Turkey
2000 BCE		Iron production begins in Anatolia. The earliest known steel is about 4000 years old and was excavated in Turkey.	
10th century BCE	Consumption	Iron working is introduced to Greece in the late 10th century BC.	Greece
6th century BCE	Facility	Blast furnaces are developed in China.	China
6th century BCE	Technology	Wootz steel is developed in India. Craftsmen in the southern part of the country use crucibles to smelt wrought iron with charcoal to produce 'wootz' steel.	India
500 BCE	Technology	The technology of iron making reaches the western limits of Europe.	Europe
400 BCE	Technology	The technology of iron making reaches China.	China
300 BCE	Technology	Wootz steel making technique develops in India and Sri Lanka. The technique spreads across the Arabian peninsula.	India, Sri Lanka
300 BCE–1700 CE	Technology	Era of the legendary Damascus Steel.	Near East
206 BCE–25 CE	Technology	The Chinese during the Han dynasty can already produce heat-treated steel.	China
2nd century BCE	Production	Early examples of high-quality steel are produced in China.	China
402 CE	Product	The Iron Pillar of Delhi is erected at around that time. It is the oldest surviving example of rust-resistant steel.	India
1100–1300	Technology	Wootz steel comes to the attention of Europeans in the form of Damascus swords, which are extremely strong, shatter-resistant and can be sharpened to a fine blade.	
12th century	Production	By the 12th century, Sri Lanka is the world's largest supplier of crucible steel.	Sri Lanka
1702		Coke is first used to smelt iron ore on a mass scale, replacing wood and charcoal which start becoming increasingly scarce.	
1712	Product	English inventor Thomas Newcomen builds the first commercially successful steam engine.	United Kingdom
1751	Production	Crucible steel is produced. English manufacturer Benjamin Huntsman develops techniques for production of high quality steel, when he establishes a steelworks at Sheffield, England, where the steel is made by melting blister steel in clay crucibles at a temperature of 1500–1600°C (2700–2900°F), using coke as a fuel.	United Kingdom
1783	Product	English ironmaster Henry Cort invents the steel roller for steel production.	United Kingdom
1784	Technology	English ironmaster Henry Cort develops puddling furnaces, which would be used by ironmakers to transform cast pig iron into a low-carbon content wrought iron.	United Kingdom
1794	Technology	Welsh inventor and ironmaster Phillip Vaughan patents the design for the ball bearing to support the axle of a carriage.	United Kingdom
1856	Technology	English inventor Henry Bessemer develops an effective way to use oxygen to reduce the carbon content in iron. The Bessemer converter (so called because it converts iron into steel) blows air through molten pig iron, which removes its carbon, making it more malleable. The interaction of oxygen and carbon generates a heat which increases the temperature of molten iron, allowing steelmakers to avoid using additional fuel. The process developed by Bessemer becomes a major breakthrough, giving birth to the modern steel industry.	United Kingdom
1860	Production	There are 3400 puddling furnaces in Britain producing a total of 1.6 million tons of wrought iron per year, about half the world's production.	United Kingdom
1860	Production	Crucible steel starts being produced in Pittsburgh, Pennsylvania, using a charge of wrought iron and pig iron.	United States
1860s	Technology	German engineer Karl Wilhelm Siemens further enhances steel production through his creation of the open hearth process, which produces steel from pig iron in large shallow furnaces.	
1860s		Following the American Civil War, the United States' steel production grows with astonishing speed, led by Scottish-American industrialist, Andrew Carnegie.	United States
1868	Technology	British metallurgist Robert Forester Mushet invents tungsten steel.	
1872	Technology	Englishmen John T. Woods and John Clark file for patent of an acid and weather resistant iron alloy containing 30%–35% chromium and 2% tungsten, effectively the first ever patent on what would now be considered a stainless steel.	United Kingdom

1875	Scientific development	Henri Aimé Brustlein from France details the importance of low carbon content in successfully making stainless steel. Brustlein points out that in order to create an alloy with a high percentage of chromium, the carbon content must remain below around 0.15%.	France
1876	Technology	English inventor Sidney Gilchrist Thomas develops a solution to the phosphorus content (a deleterious impurity that makes steel brittle) by adding a chemically basic flux – limestone – to the Bessemer process. The limestone would draw phosphorus from the pig iron into the slag, allowing the unwanted element to be removed.	United Kingdom
1883	Product	The Brooklyn Bridge – the first steel suspension bridge, is inaugurated in New York City.	United States
1885	Product	The Home Insurance Building – the first steel skyscraper, is completed in Chicago.	United States
1895	Technology	German chemist Hans Goldschmidt develops the aluminothermic reduction process for producing carbon-free chromium, thus prompting a major boost in the development of stainless steels.	
1904	Scientific development	French metallurgist Léon Guillet undertakes extensive research on many iron-chromium alloys.	
1907	Technology	The first commercial electric arc furnace (EAF) is established in the United States. Today, almost all stainless steel is produced using the EAF method.	United States
1908	Scientific development	Frederik Becket of the Electro Metallurgical Company at Niagara Falls, New York develops a low-carbon ferrochromium produced by reducing the chromium oxide with silicon instead of aluminium. Over 80% of the world's ferro chrome today is utilized in the production of stainless steel.	United States
1909–1912	Scientific development	Eduard Maurer and Benno Strauss at Krupp laboratories develop high-chromium nickel steels.	Germany
1911		Germans P. Monnartz and W. Borchers discover the correlation between chromium content and corrosion resistance, stating that there is a significant boost in corrosion resistance when at least 10.5% chromium was present. The pair also publishes detailed works on the effects of molybdenum on corrosion resistance.	
1911	Scientific development	American metallurgist Elwood Haynes experiments with high-chromium steels to determine the effect of chromium on corrosion resistance, hardness, elasticity, and cutting qualities. In the same year, Christian Dantsizen of General Electric Research Laboratory also begins experimenting with high-chromium steels for possible commercial development.	United States
1912	Scientific development	English metallurgist Harry Brearley, working in the Brown-Firth research laboratory in Sheffield, England, discovers a martensitic stainless steel while attempting to develop an erosion-resistant alloy for military applications. In 1913 Brearley melts the first commercial chromium steel as a stainless steel for cutlery blades. Harry Brearley is credited with the invention of stainless steel.	United Kingdom
1913	Scientific development	English researcher Harry Brearley creates a steel with 12.8% chromium and 0.24% carbon, argued to be the first ever stainless steel.	United Kingdom
1914	Scientific development	Ludlum Steel Co. metallurgist P.A.E. Armstrong discovers chromium-silicon steels, when a small electric furnace is accidentally contaminated due to some silicon reduced from the asbestos cover on the electrode.	United States
1917	Scientific development	Charles Morris Johnson of the Crucible Steel Company, begins investigating chromium-nickel-silicon steels, which are later patented under the name Rezial.	United States
1919	Technology	American metallurgist Elwood Haynes obtains a patent on martensitic stainless steel.	United States
1919–1923	Product	Cutlery in Sheffield, England start regular production of stainless steel cutlery, surgical scalpels and tools. Early stainless tableware such as dishes and bowls also start to appear at this time.	United Kingdom
1929	Technology	Luxembourgish metallurgist William Justin Kroll discovers precipitation-hardening stainless steel.	
1930	Technology	Avesta Ironworks from Sweden produces duplex stainless steel for the first time, with the microstructure of the alloy consisting of both ferrite and austenite.	Sweden
1930	Technology	The Chrysler building is completed in New York City. It is the first to feature stainless steel roof cladding, which still shines like on its first day.	United States
1935	Technology	Sinks made of 18-8 stainless steel begin to be installed in new houses, instead of porcelain-enamelled cast iron sinks.	

1950	Technology	Basic oxygen steelmaking (BOS) is introduced, limiting impurities and even processing old scrap metal into steel, lowering wastage and increasing efficiency. The BOS process would make the Bessemer Process and other steelmaking processes that developed alongside obsolete. These days, BOS accounts for the majority of steelmaking processes in the industrialized world.	
1960s	Technology	A method to separate oxygen from nitrogen on an industrial scale is developed in the decade. This would allow for major advances in the development of basic oxygen furnaces.	
1989	Technology	Ferritic stainless steel is first used as a large-scale roofing material.	
2001	Technology	The last open-hearth furnace in China closes.	China
2006	Production	China becomes the biggest stainless-steel producer in the world.	China

Fig. 7 A painting by Charles Sheeler illustrates changing subjects and landscapes.

The above time line clearly establishes the evolution of Steel as a structural material and also highlights other consumer use and application vis a vis stages of civilization. However, this paper would like to restrict itself to very basics of the Material Steel in relationship to the construction industry. The chronological timeline of Steel clarifies the understanding of steel as a manmade invention – a designed material that has evolved according to the need of the society to suit various purpose and designed intention. The previous sections of this paper have further elaborated on the subsequent widespread use of steel that has been supported by and has supported the development of human civilization itself.

The properties of steel result from its chemical composition and methods of manufacturing. Depending on the intended use case and existing product standards – steel can be designed to have a varying range of yield-strength, ductility, malleability, toughness and weldability.

Fig. 8 A painting by J.M.W. Turner illustrates the industrial landscape.

Fig. 9 The central atrium of the Lloyds Building, London.

While this immensely increases the varieties, forms and usability of steel – this makes the production process highly specialised and energy intensive. This means that steel in its various forms has a relatively high value of embodied energy compared to other natural materials.

The high embodied energy necessitates an awareness that while steel gives us unparalleled freedom, this freedom comes with an added responsibility to rationalise its use. This means that there needs to be creative, out-of-the-box approaches that maximise its longevity, its use and its overall efficiency – keeping in mind that only then can the material justify its high initial energy liability. The following section discusses the possibilities and potential advantages of steel.

Reliability

Most of our conventional construction materials have a limited range of strength and apart from Timber, most are usually weak in tensile strength. Natural materials that are commonly used for structural supports are Stones, Bricks, etc. They are very

Fig. 10 Structures inspired by learnings from nature.

Fig. 11 Structures inspired by learnings from joineries in other materials.

good in compression and thereby provide stability. However; in most structure systems there is the issue of transferring the superimposed load through the horizontal members – slabs, beams etc. to the vertical supports. Stones and bricks can also bridge spans to a limited extent, but they prove to be impractical as the dead load of the structure also increases. Therefore, in ancient times timber has been used to extensively as horizontal connections. Later, innovations in the fabrication process has made it possible to create trusses. This has allowed for accommodation of larger spans using relatively lesser quantity of materials.

We have been extremely resourceful and have managed to use innovative modes of spanning through arches, domes and vaults, or materials such as bamboo or timber. However, slowly their design limitations have come to the foreground, particularly in the present context where we need large uninterrupted spans. Simultaneously there has been an increasing need for taller and taller buildings with an ever-increasing vertical load that are impractical to design by using traditional construction materials.

Steel in its various forms have helped us find solutions and respond to this need, and therefore has been intensely propagated as a designed constructional material for supporting very large spans and for intense loading. Steel has the maximum strength to weight ratio and therefore provides a wide range of choice. It also helps to expand the structural capability of natural materials. Reinforced concrete is another manmade construction material, which gains inherent strength due to incorporated steel members. The ability to explore and support various structural systems has made Steel one of the most RELIABLE materials. The Eiffel tower

Fig. 12 The Eiffel Tower, Paris.

Fig. 13 The Nest Olympic Stadium, Beijing.

in Paris ([Fig. 12](#)), The New London Bridge designed by Fosters or the Nest Olympic stadium in Beijing ([Fig. 13](#)) is a testimony of its reliability.

Versatility and Adaptability

The strength of a material is manifested through various types of structural design options, construction technology and processes of implementation. These are widely varied in Steel. Depending on the type of requirements, steel has a range of forms and types that suit various design implications. They are:

- As-rolled steel,
- Normalized steel,
- Normalized-rolled steel,
- Thermo mechanically rolled (TMR) steel,
- Quenched and tempered (Q&T) steel.

In response to the special needs for enhanced durability, health and fire requirements etc. special steel of appropriate grade has been presently developed making it more environmentally responsible.

Versatility and adaptability of a structural material plays a very important role in the design of innovative, explorative structural systems that are efficient, cost effective and practical in a given context and can be implemented within an acceptable time frame.

Beside large-span structures there is also the added complexities associated with vertical structural typologies such as requirements of high wind pressure, seismic factors, structural fatigue etc. These complicated structural issues can only be mitigated through intelligent choices of structural systems where they perform as groups of smaller components that are connected, joined to provide a strong, reliable, adaptable structural matrix. In this system the final strength is derived through an efficient distribution and dispersal of loads incorporating a complex system of components, nodes and connections. Various such construction systems have been evolved utilizing steel for very large span structures like bridges, aqueducts, viaducts etc. such as systems of steel girders, cable-stays. Other systems such as space frames, geodesic domes or tensile structure have evolved for spanning large exhibition spaces and pavilions. Special forms and shapes have been conceived for multistoried buildings and skyscrapers. These innovations are often inspired from natural forms and

Fig. 14 The World Trade Centre, New York.

Fig. 15 30 St. Mary Axe Building, London.

their structural networks. Such inspiring forms and their development can be seen in the evolution of the World trade Center ([Fig. 14](#)), Chrysler Building, John Hancock center and the 30 St Mary Axe Building ([Fig. 15](#)).

Reusability and Recyclability

The best extent of adaptability of Steel is realized when it can be combined to extend the capability of traditional construction methods and enhance its life cycle, as well as innovate new construction methods like reinforced concrete, pre-stressed and post-tensioned concrete etc. This adaptability is the main reason that steel has become the key material choice in all forms of

Fig. 16 Using a steel structure with tensile components for a lightweight large span structure.

construction that builds on and strengthens existing assets – such as in the retrofitting of old buildings, infrastructures, etc. The use of steel can extend the life cycle of these assets, thereby rationalizing energy demand and minimizing waste generation.

Steel components are very durable and maintainable. Steel construction has numerous components assembled in a designed manner to systematically distribute the forces through these components, connections and joints. This makes it possible to dismantle the entire system and reuse a large number of the parts. Effectively this means that steel has an extended life cycle. The high degree of reusability also means that construction and demolition waste generated is vastly less. Even if some components cannot be reused as is, or are scraps, they can again be melted and recycled to form other components. It has been estimated that the entire framework of a residential house can be built from the recycled scraps of just eight recycled cars.

Construction Advantage

Construction today needs speed and transportability to meet the demands of ever-increasing urbanization. Steel construction has the highest ratio of strength versus weight, and essentially lighter footprint than conventional construction. Thus, it has a lesser impact on ecology and is less disruptive. Steel – in its entire life cycle has comparatively lesser embodied energy and is thus a GREEN OPTION (Fig. 16).

Steel construction is essentially fabricating pre-engineered components into a designed order for required strength, durability and purpose. Therefore, it involves detailed planning right from design, processing, fabrication and final installation. Components in this system have to be manufactured to meet specified norms, standards and be of required shape, size, and strength to a high degree of accuracy. This necessitates better and more efficient quality control mechanisms for timely production along with all required accessories that adhere to best practices norms. The components are fabricated, transported to designated sites and assembled as per engineering drawings. This process also ensures the extent of construction work on site, creating minimum disturbance to the local context and its surrounding areas. This reduces construction pollution and therefore becomes a SMART CHOICE.

Conclusion

Physical designers, planners, urban designers and the decision makers have to make a responsible choice in holistic ways that balances the needs of development with those of ecology, environment, energy, cost and local socio- cultural contexts. Therefore, the materiality of construction also needs to be assessed and evaluated for its sustainability quotient. Historically, this article has elaborated on how technological advancements in steel have happened concurrently with various stages of development, construction methodology and implementation. Its continued practice has been a responsible choice. Today, new consciousness and awareness of development concerns have made the design and planning process more restrictive. Steel as a flexible, adaptive material with a wide range of mechanical properties, chemical composition and innovative fabrication processes provides us an avenue that combined with the wisdom of being responsible can chart out a path for sustainable future development.

Using Construction and Demolition Waste Materials as Construction Materials for a New Building

Madhumita Roy, Jadavpur University, Kolkata, India

© 2020 Elsevier Inc. All rights reserved.

Introduction

Global Construction 2030, a new report prepared by Global Construction Perspectives and Oxford Economics, sponsored by PwC forecasts that the volume of construction output will grow by 85% to \$15.5 trillion worldwide by 2030, with majorly three countries i.e., China, US and India, leading the way and will account for 57% of all global growth. Cities are changing its volumetric profiles throughout the world and India is of no exception. Burgeoning population is creating pressures in cities which in turn compelling the city skylines to have a drastic change in all aspects like land use pattern, height profile, density, socio-economic context etc. The single family houses are converting into multi-family gated communities. The load bearing, low-rise structures are changing into high-rise frame structures which are continuously forcing our cities and neighborhoods to hold this change. This change is giving rise to a huge amount of demolition and construction waste. The primary reasons towards the increase of Demolition and Construction Waste are: (1) Redevelopment, renovation and repair of old building stock, bridges, large scale projects; (2) New development for better economic growth; (3) Debris arising out of some kind of natural or man-made disasters like earthquake, cyclone, floods and fire etc. Higher densities in brownfield areas of cities not only demand for more and more construction materials but also generating a huge quantum of waste on a daily basis. Policy makers are framing rules to incorporate solar panels to buildings in order to facilitate sustainable development. The estimated lifespan of a solar panel is 25–30 years whereas the market is mostly captured by cheap Chinese make panels which never ensure a longer life. In a recent survey, the International Renewable Energy Agency estimated that there were already 250,000 metric tons of solar panel waste worldwide and that this number would grow to 78 million by 2050.

Waste materials have been a great concern for Environmental pollution. Government systems in all countries are spending lot of energy and money in handling the waste further adding pollution to the environment. Illegal dumping of these waste materials into waterbodies, water channels further aggravates the situation. On the other hand, demand and supply of construction materials are also matters of concern. Researchers and Designers are trying to think about the solutions about how to use the waste materials as alternative building material.

In India, the construction industry has attained a steep growth in the recent decades due to the increasing population and growing demand for infrastructure, industry and commerce. The demand for new construction results in demolition of existing structures/built forms. The production of waste materials due to demolition of structures ([Fig. 1](#)) becomes a burden to the management. In addition to this, a huge amount of construction waste is also there. There is an urgent need of management of Construction and Demolition (C and D) waste which is very distinct from Municipal Solid waste. The matter being relatively a new issue in the country, there is hardly any proper database regarding the quantity of waste generation occurs in India. There is nil regulatory framework nor any strict enforcement. *Environmental issues such as increase in the flood levels due to the illegal dumping of construction and demolition waste into the rivers, resource depletion, shortage of landfill and illegal dumping on hill slopes are evident in the metro cities* ([Mullick, 2014](#)). This paper intends to find out the present status

Fig. 1 Waste generated due to demolition of structure.

of Government intervention in handling waste in the country, to identify probable waste materials which can be used as construction materials and their possible ways of use in the production of new stock of buildings.

Components of C and D Waste

C and D (Construction and Demolition) waste is defined in slightly different ways by different countries. For the purpose of this study, the definition used by the Ministry of Environment and Forests, Government of India is being adopted. As per the Notification S.O. 908(E) dated the 25th September 2000 issued by MoEF, the (D and C) “*demolition and construction waste*” means wastes from building materials debris and rubble resulting from construction, re-modeling, repair and demolition operation. In most cases ‘Construction and Demolition’ waste are coupled together but there are differences between demolition and construction waste. Waste may be categorized into two groups: (1) Construction waste (2) Demolition waste.

Construction Waste

Construction waste is newer, cleaner and easy to segregate and recyclable. Construction waste tend to be more homogenous. The materials which are observed and estimated as part of the construction waste component are listed in the [Table 1](#) (See “Relevant Websites section”).

Demolition Waste

The demolition waste materials tend to be mixed with a variety of materials, and difficult to separate and recover. Further categorization is also possible but for this study it is being restricted to only broad demolition waste category. The materials which are observed and estimated as part of the demolition waste component are listed in [Table 2](#) (See “Relevant Websites section”).

Quantifying the Total C and D Waste Generation in India

There is no general agreement regarding the total volume of construction and Demolition waste generated annually in India till date. TIFAC calculation for waste from the construction industry accounting for 25% of solid waste or 12–15 million tonnes per annum. The data in TIFAC study report in 2001 found to be quite an underestimated amount by several researchers time to time.

Table 1 Construction waste component

<i>Component</i>	<i>Material description</i>
Excavated earth	Earth accumulated due to excavation work for foundation
Wood	New wood which may includes plywood, chipwood, shavings and sawdust
Masonry	Inert materials like brick, concrete, rock, and dirt, etc
Metal	Metallic materials consisting metal studs, reinforcement bars, beams, pipes, paint containers etc
Plastic	Plastic materials including PVC pipes, doors, insulation material, plastic sheet, paint containers etc
Cardboard	Cardboard boxes, box board, various packing material, etc
Glass	Very less quantity if broken
Others	Any other material which is not included into the list mentioned above

Table 2 Demolition waste component

<i>Component</i>	<i>Material description</i>
Excavated earth	Earth mixed with foundation material
Wood	Weathered wood typically painted and attached to some other materials
Masonry	Inert materials like brick, concrete, rock, and dirt, etc mixed with other materials
Metal	Metallic materials consisting metal studs, beams, pipes, paint containers etc
Plastic	Plastic materials including PVC pipes, doors, insulation material, plastic sheet, paint containers etc
Paper	Cardboard boxes, various packing material, etc
Glass	mostly broken mixed with painted ones and in fixed condition alongwith doors/windows
Asbestos	Torn off shingles
Rubber	
Others	Any other material which is not included into the list mentioned above

Table 3 Generation of C and D waste by different cities in India

City	Population	Annual C and D generation (Million tonnes/annum)
Mumbai	12,442,373	0.75
Delhi	16,787,941	1.38
Bengaluru	8,443,675	0.26
Chennai	6,500,000	0.75
Kolkata	4,496,694	0.48
Jaipur	3,471,847	0.06
Patna	2,514,590	0.08
Ahmedabad	6,063,047	0.21
Bhopal	1,917,051	0.02
Coimbatore	2,618,940	0.03

Table 4 Generation of C and D waste by other countries

Country	Income based country classification (World bank)	Population	Million tonnes/year	Year
Australia	(HIC)	24,125,848	19	2014
United States	(HIC)	322,179,605	534	2014
UK	(HIC)	65,788,574	66.2	2016
Germany	(HIC)	81,914,672	223	2005
China	(HIC)	1,403,500,365	200	2005
Japan	(HIC)	127,748,513	77	2012
South Korea	(HIC)	50,791,919	61.7	2013
India	(LMI)	1,324,171,354	100	2018

Source: Data collected from various internet sites.

In 2010, MoEF mentioned about the annual C and D waste as 10–12 million tonnes. The Central Pollution Control Board announced it as 12 million tonnes in 2011 whereas in 2017 the estimate reached to 25–30 million tonnes. Another survey conducted for 10 cities in the year 2015 by GIZ and DA also reinforced the fact that the TIFAC estimate was significantly low (**Table 3**) (MoHUA-NITI Aayog, 2018). The document 'Utilization of Recycled Produce of Construction and Demolition Waste: A Ready Reckoner' prepared by BMTPC, MOHUA in 2018 shows that around 100 million tonnes seems to be the approximate generation per annum throughout the country. The data is based on 2011 census with existing housing stock of 110,139,853 in urban areas and 220,695,914 in rural areas coupled with rate of renovation and new construction of 5.75 billion sq. m. area during the period 2005–2012. Thus it is a fact that there is a gross uncertainty in assessing the total quantum of C and D waste generation either per month or annually.

Table 4 shows that excepting India, all other countries fall into the 'High Income' category whereas India only falls into 'Lower Middle Income' category. US, China and India having higher population figure display a very varied account regarding C and D waste generation.

The calculation of C and D waste generation in case of new construction will be very different from an old construction waste generation. It is also dependent on the volume and nature of construction also. It will vary in case of *pucca*, semi-*pucca* and *kucca* construction. However, according to the thumb rule calculation by TIFAC, a new construction generates 40–60 kg of C and D waste per sqm. India must have generated an average of 576 million tonnes of C and D waste in 2013 itself. It was also mentioned that the C and D waste generation due to demolition and repair/renovation of older stock would be 10 times more than the generation from new construction. CSE report estimation shows that the total C and D waste generated by buildings alone in 2013 amounts to 626 million tonnes, 52 times higher than official estimate. This figure will again go up if the C and D waste generation from bridges, road construction is further added. In 2015, whereas CSE estimated a figure of 531 million tonnes per year using McKinsey & Company's report. All published documents mentions about the gross discrepancy regarding the data towards the total C and D waste generation in the country which is without any scientific base and thus there is no denying the fact that there is an urgent need to have a realistic figure and proper estimation in this regard in order to derive a clear roadmap about the actual stock in future.

Composition of the C and D Waste

As per the C and D waste management toolkit document prepared by CPCB, MoEF, MoHUA and NPC in 2017, in India, it is estimated that the amount of C and D waste generated due to different activities in the following manner:

Fig. 2 Percentage distribution of C and D waste generation.

Table 5 Typical Composition of C and D waste in India

Material	TIFAC (%)	MCD (%)	ILFS (%)
Soil, Sand and Gravel	36	43	31.5
Brick and Masonry	31		
Concrete	23	35	–
Metals	5	–	0.4
Bitumen	2	–	–
Wood	2	2	1.5
Others	1	1	7.6

Source: Available at: www.irjet.net.

- An average generation of 500 kg and 300 kg per sqm on account of pucca and semi-pucca building respectively.
- Waste generation during construction around 40–60 kg per sqm.
- During repair/renovation work, it is around 40–50 kg per sqm.

This assumption is almost in tune with the TIFAC data. Waste generation during repair/renovation construction would be much higher depending on the quantum of work and type of construction. However, it is found that this figure is being used in all the documents for the purpose of calculation of waste generation. According to Danish Environmental Protection Agency (DEPA), 2003, 30% of the total solid waste generated was from C and D waste. Of this 70%–75% waste generated was from demolition activity, 20%–25% from renovation and remaining 5%–10% from new building developments (**Fig. 2**). It is very difficult to categorise the composition of the C and D waste especially from demolition waste. However, TIFAC, MCD and ILFS have identified some of the materials broadly as follows in **Table 5**.

The composition of the collected C and D waste is an important data with respect to the creation of databank regarding the stock of raw materials required for construction purpose. NGT has recently issued an order against all sand mining activity being carried out across the country without environmental clearance which means the availability of sand has become scarce now. The same problem lies with the availability of brick also. On the other hand “India needs to build 31,000 new houses a day over the next 15-years to meet the needs of its rapidly growing and urbanising population” a report says. “The demand for aggregates in 2007 has seen an increase by five%, to over 21 billion tones, the largest being in developing countries like example India”. (Study by Asian Institute of Technology (AIT), Thailand for some Asian countries included India, report released in May 2008). The regular flow of raw materials in the construction sector will help to regulate the steady supply of the burgeoning demand of housing stock. Recycling, Reusing the C and D waste might fill up the gap. Thus the generation of C and D waste should not be looked as a burden, rather should be utilized as a facilitating raw material resource in construction sector. At the same time, the actual calculation of the C and D waste generation should be made simultaneously without any further delay.

Policies and Framework in India

Standards and Certification

Any alternative material intended to be used for construction purpose needs to be approved by an authorized agency. A list of approved material which can be used for various purpose of construction is mentioned in various codes and standards. The National Building Code of India (2016) allows for the use of recycled aggregates in certain applications and also mentions in **Box 1** as follows:

Box 1 National Building Code (NBC-CED 46) of India 2016: Part 11 of NBC 2016 'Approach to Sustainability' (article 11), states that:

Recycled Coarse Aggregate may be used in concrete for bulk fills, bank protection, base/fill of drainage structures, pavements, sidewalks, kerbs and gutters, etc.

Up to 30% of natural crushed coarse aggregate can be replaced by the recycled concrete aggregate.

This percentage can be increased up to 50% for pavements and other areas which are under pure compression specific to the standards and practices pertaining to construction of roads.

The Indian Roads Congress (IRC) has issued 'IRC-121:2017 Guidelines for Use of C and D Waste in Road Sector' mentioning about the kind and proportion of materials from recycled C and D waste which can be safely used for specific road construction/repair applications.

Guidelines and Advisories

The constitution of India has provisions for the protection and improvement of the environment. The Environment (Protection) Act, 1986 defines environment as *"environment includes water, air and land and the interrelationship which exists among and between air, water and land and human beings, other living creatures, plants, micro-organism and property"*. In 1986, Environmental Protection Act (29 of 1986), Section 6 and 25 mentions briefly about 'other wastes' and 'recycling'. C and D waste finds a brief mention in Schedule III of the Municipal Solid Waste (Management and Handling) Rules, 2000 and the "Manual on Municipal Solid Waste Management" of the MoUD, 2000 has a article on C and D waste which lays down basic guideline on its handling. Municipal Corporation of Greater Mumbai has notified Construction and Demolition and Desilting Waste (Management and Disposal) Rules 2006. National Environmental Policy in 2006 prepared by MoEF, there are few mentions about waste handling vide Sections 4 and 5.4. The Working Committee (2010) on Municipal Solid Waste Management recommended that this issue may be addressed specifically with due focus and attention.

In 2012, the Ministry of Urban Development (MoUD), vide its Notification dated June 28, 2012 directed all states to set up environment friendly CDW recycling facilities in all cities/towns with population of over 1 million. The MoUD report, 'Technical Aspects of Processing and Treatment of Municipal Solid Waste', under Swachh Bharat Mission also recognized the need for CDW Management.

Central Public Works Department's (CPWD) introduced 'Guidelines for Sustainable Habitats' in the year 2014 wherein a set of 'Guidelines on re-use of recycled C and D waste' was included. The Draft Solid Waste Management Rules, 2015 published by MoEF&CC vide GSR 452(E) dated 3rd June 2015 had a separate article on C and D waste. Subsequently, the draft rules culminated into C and D Waste Management Rules, 2016 issued by MoEF&CC vide notification no. GSR 317(E) dated 29th March 2016.

In 2016 BMTPC prepared the 'Guidelines for Utilization of Construction and Demolition Waste in Construction of Dwelling Units and Related Infrastructure in Housing Schemes of the Government' and highlighted the considerable shortage of conventional and traditional building materials in India based on high demand for building materials by 2021–2022.

The Ministry of Housing and Urban Affairs (MoHUA), vide a letter dated March 23, 2016 circulated a notification by CPWD on mandatory use of recycled portions of C and D waste in construction activities, if the same is available within 100 km of the construction site.

Delhi PWD issued an advisory to all Delhi Government Departments in 2015, mandating a minimum of 2% and 10% use of recycled C and D waste products in building construction and road works respectively. The advisory was reissued by the Delhi PWD in 2018. Use of Construction and Demolition waste 20%–100% is allowed in construction. IS-383 standard code revised. Bureau of Indian Standards (BIS) has issued 3rd amendment to IS-383:2016 "Coarse and fine aggregate for concrete" to include fine and coarse aggregate produced by processing of C and D waste. India Road Congress (IRC) has issued IRC-121:2017 Guidelines for use of C and D waste roads sector.

Source of C and D Waste Generation

As per C and D Waste Rule 3 (j) "waste generator" means any person or association of persons or institution, residential and commercial establishments including Indian Railways, Airport, Port and Harbor and Defense establishments who undertakes construction of or demolition of any civil structure which generate construction and demolition waste. In general, broadly two types of C and D waste generators are considered namely (1) Bulk Generator and (2) Small Generator which is shown in Box 2.

As per C and D Waste Rule, Waste generators who generate more than 20 tons per day OR 300 tons per project in a month are considered as Bulk Generators and they shall segregate waste into 5 streams namely (1) Concrete (2) Soil (3) Steel (4) Wood and plastics (5) Bricks and mortar. Construction sources again consists of two broad areas which are (1) infrastructure development sector and (2) the real estate housing sector. Infrastructure Development Sector includes roads, bridges, airport/runways and any

Table 6 Origin and causes of construction waste

Origin of waste	Causes of waste
Contractual	• Errors in contract Document • Contract document incomplete at commencement of construction
Design	• Design changes • Design and construction detail errors • Unclear unsuitable specifications • Poor coordination and communication (late information, last minute client requirements, slow drawing revision and distribution)
Procurement	• Ordering errors (ordering items not in compliance with specification) • Over allowances (i.e., difficulties to order small quantities) • Supplier errors
Transportation	• Damage during transportation • Insufficient protection during unloading • Inefficient methods of unloading
On-site management and planning	• Lack of on-site waste management plans • Improper planning for required quantities • Lack of on-site material control • Lack of supervision
Material storage	• Inappropriate site storage space leading to damage or deterioration • Improper storing methods • Materials stored far away from point of application
Material handling	• Material supplied in loose form • On-site transportation methods from storage to the point of application • Inadequate material handling
Site operation	• Accidents due to negligence • Equipment malfunction • Poor craftsmanship • Time pressure
Residual	• Waste from application processes (i.e., over preparation of mortar) • Packaging
Other	• Weather • Vandalism

Table 7 Components of C and D waste

Major component	Minor component
Cement concrete	Conduits
Bricks	GI pipes/Iron pipes/plastic pipes
Cement plaster	Electrical wires/conduits/fittings
Steel from RCC	Panels
Wooden doors & windows	Asbestos and contaminated soil
Aluminum windows & doors	Glass
PVC doors & windows	Plastic carry bags, sachets of tobacco and other plastics, clothes, cement bags, gunny bags, thermocol, etc.
MS grill, window frames	Trees, plants
Roofing support system	
Rubble	
Timber, etc.	
Stones & Clay (soil from excavation)

activity related to the development of infrastructure whereas real estate sector includes the mass housing, shopping malls, healthcare, etc.

Among so many reasons behind the generation of C and D waste, six major causes of waste are design, procurement, materials handling, operation, residual, and other. A recent research that covered C and D waste generation indicated that 33% of on-site waste is due to architects' failure to implement waste reduction measures during design stage. According to Dajadian and Koch, a list of origin and cause of construction waste is mentioned below in [Table 6](#).

According to [Dajadian and Koch \(2014\)](#); Origin and causes of construction waste.

Components of C and D Waste

C and D waste has been classified into two major components as per the Toolkit for C and D waste management 2016 as shown in [Table 7](#).

Waste Handling Options

Across the globe, the waste management sector follows a generally accepted hierarchy. The concept of 4R referring to Reduce, Reuse, Recycle and Recover particularly in the context of production and consumption is very familiar today in most of the developed countries. Re-use and recycling of some materials and resources are becoming industry standard practice ([Fig. 3](#)).

Table 8 Recycled materials and possible applicability

Sl. No.	Product name	Sample image	Probable uses
1.	Ready mix concrete		Can be used in all types of construction work
2.	Hollow bricks		Can be used in any type of building construction
3.	Pavement blocks		● Parking pavements ● Pedestrian pathways ● Passageway
1.	Tiles		
1.	Checkered		Can be used in ● Lobby area ● Footpaths ● Entrance ● Stair-cases of public buildings ● Passages of auditoria and storage godowns
2.	Brick		● Can be used as a cladding material for façade ● In interiors

(Continued)

Table 8 Continued

Sl. No.	Product name	Sample image	Probable uses
3.	Dumble		Can be used in ● Footpath ● Outdoor pavement
4.	Wall		Wall Cladding both in ● Interior ● Exterior
5.	Interlocking		Can be used in ● Footpath ● Outdoor pavement
6.	Tech tile		Covering roofs, floors, walls, or other objects such as tabletops
7.	Kerb stones		Used at raised pavements, sidewalks and footpaths

Table 8 Continued

Sl. No.	Product name	Sample image	Probable uses
II	Raw material		
1.	Granular sub base (GSB)		Are used usually as crushed stone, crushed slag or concrete, or slate
2.	Manufactured sand		Manufactured sand have been regularly used to make quality concrete
3.	Aggregates 5–10 mm		Used as base material under foundations, roads, and railroads
4.	Aggregates 10–20 mm		Can be manufactured as per customer requirements
5.	Loose soil/excavated soil		For land filling purpose

(Continued)

Table 8 Continued

Sl. No.	Product name	Sample image	Probable uses
6.	Jali		Can be used in a similar manner as other kind of 'Jali' products available in the market
7.	Drain cover		Can be used in a similar manner
8.	Boundary wall		Various other design options can be made

Primary source: Toolkit for C and D waste management 2016.

Waste Reduction

Waste reduction is the most preferable option of waste management. Every effort should be made towards reduction of waste at the generating points through careful design, construction practices and management. It will bring two-fold benefits in mitigating greenhouse gas emissions. Firstly it will help to avoid the emissions associated with the product manufacturing process and secondly the direct emission involved with the conventional waste management activities.

Waste Reuse

Reusing the C and D waste can save huge amount of natural resources and also can reduce carbon footprint. Disposal of C and D waste into landfills would also be minimized.

Waste Recycling

The principal factors for recycling of Construction and Demolition waste in the building industry are growing concern for environmental protection, conservation of natural aggregate resources, shortage of land for waste disposal, and increasing cost of waste treatment. The reuse of recycled materials derived from construction and demolition waste is growing all over the world.

Table 9 Energy intensities with the recycling process of different building materials

Building materials	Recycled content (%)	Production energy unit for recycle process (MJ/kg)
Aluminum	81	108.6
Asphalt	30	7.32
Concrete	30	0.805
Glass	100	11.9
Reinforcing bar	100	21.6
Stainless steel	100	11
Galvanized steel	100	32.75

Fig. 5 Fencing done with the waste sheet left over after the laser cutting of metal components. Source: Pushing the boundaries: Fence materials and design. Available at: <https://renew.org.au/>.

Recovery

The recovery of waste and the use of recovered materials should be encouraged widely in order to conserve natural resources. Waste must be recovered without endangering human health and without the use of processes or methods likely to harm the environment. Recovery operation generally implies a prior treatment of the waste.

Recycled C and D Waste Products and its Applications

Construction accounts for 65% of the total investment in infrastructure. Investment in construction accounts for nearly 9% of India's Gross Domestic Product (GDP). This sector is likely to have a steep increase because of Government of India's recent initiative in allowing 100% Foreign Direct Investment in Real Estate Sector. Thus the demand for building materials will increase undoubtedly. Some of the products and possible applications are shown in Table 8.

Fig. 6 Wrought iron fences. Source: Pushing the boundaries: Fence materials and design. Available at: <https://renew.org.au/>.

Fig. 7 Rock Garden, Chandigarh.

Energy Implications

Life cycle assessment (LCA) of buildings is to be carried out properly to evaluate the impacts of buildings on the environment in coming days. Within this framework, Life Cycle Energy Analysis (LCEA) needs to be applied to evaluate all energy uses by a building over its life cycle which mainly consists of manufacturing phase, operation phase and demolition phase. During the calculation process, the optimization of energy use in each and every component and activities will be required. The present day casual practices would be replaced by a more professional quantifiable approach through which all stakeholders involved in the construction process of a building would remain aware about the energy balance in a building (Fig. 4). Thus, the careful selection of building materials out of the whole reserve either natural, manufactured or recycled will make a big difference in retaining a sustainable environment (Table 9).

Some Case Examples

Mara Ripani of Village Dreaming talked about some possible ways of using recycled plastic and wood-plastic composites, metal, stone and living plants. Fencing or boundary wall designs could be made using steel sheet, aluminum or cast iron (Fig. 5).

These materials are non-renewable but very much recyclable. It is a known fact that air-dried sawn hardwood has a very low embodied energy cost of 0.5 MJ/kg, compared to galvanized steel 38.0 MJ/kg and aluminum 170.0 MJ/kg. A metal fence will outlast a longer time compared to any natural material and also a greater mass of natural material would be required to get a similar strength of metal fencing (Fig. 6).

Fig. 8 Collage House, Mumbai-India. *Source:* Available at: <https://www.facebook.com/spsarch>.

The Rock Garden in Chandigarh, India was designed in the year 1957 using natural and recycled or waste materials (**Fig. 7**).

According to S+PS Architects in Arch Daily, this house has a facade made from the doors and windows of homes that were demolished in the city. The project has made use of other recycled materials, including 100-year-old salvaged stone columns, flooring made from the beams of old houses, fabric waste and waste slivers of cut stone (**Fig. 8**).

Conclusion

The construction industry is one of the most polluting in the globe and people always try to hide the debris and filthy waste from sight. The economic and environmental benefits to be gained from C and D waste reduction and recycling are enormous, and it will benefit both the environment and the construction industry in terms of cost savings. Architects, Engineers and designers can take this as a challenge and turn this waste into valuable resources for using it into the construction again in an innovative way. New architectural ideas and design techniques would enrich various possibilities and enhance further scope in this sector. The C and D debris if properly managed can become a major source of construction material.

Advanced Polymeric Coatings and Their Applications: Green Tribology

Pixiang Lan, ATSP Innovations, Champaign, IL, United States

Emerson E Nunez, Universidad Autónoma de Occidente, Cali-Valle, Colombia

Andreas A Polycarpou, Texas A&M University, College Station, TX, United States

Introduction

Recent advances in polymer engineering, such as new emergency materials and new coating technologies enable broader applications of polymeric coatings. Three types of functional coatings, namely tribological coatings, hydrophobic coatings and self-healing coatings have been widely investigated, and summarized in this article.

Tribology has emerged as a field that contributes to the development and implementation of materials that are sustainable, from an energy and environmental point of view. Sustainable materials from the point of view of green tribology are those materials that can diminish friction and wear of interacting surfaces, minimize heat dissipation, and thus lower pollution. Through the development of self-lubricating materials, wear can be minimized and contribute to a greener environment by increasing the life cycle of sliding materials (tribopairs), causing a positive impact in environmental degradation, by decreasing the waste and recyclability cycle (Sasaki, 2010; Anand *et al.*, 2017). Environmentally friendly tribomaterials in the form of self-lubricating advanced polymeric coatings contribute to a greener environment by reduction or complete elimination of liquid lubricants at the sliding interfaces, thus reducing emissions, and in turn less pollution to the atmosphere.

High bearing polymer coatings based on PEEK, PTFE, ATSP and their blends have emerged as a cost-effective solution for friction and wear problems of sliding interfaces that must operate in the absence of lubricant. Experimental results show that the friction coefficient (COF) at a polymer/metal interface is governed by solid lubrication in the form of third bodies, even at values lower than those found in metal/metal interfaces in the boundary and mixed lubrication regimes (Demas and Polycarpou, 2008; Nunez *et al.*, 2010; Akram *et al.*, 2013), thus contributing to a greener environment (less power consumption). In addition, these advanced polymeric coatings have been applied in aggressive tribological applications, such as cryogenic conditions, and in space applications, where materials have to be able to withstand sliding under non-traditional conditions, making their design challenging (Gao *et al.*, 2018). The purpose of this book chapter is to provide an insight of the recent trends in the design of advanced high bearing blended polymer coatings, as viable candidate solutions for aggressive tribological applications in demanding contemporary industries, and their contribution to a greener environment.

Superhydrophobic coatings exhibit low surface energy, and when water rests or slides on the surface, it absorbs dust and together slide off the surface: this phenomenon is called self-cleaning. The self-cleaning property can save cost for cleaning, when superhydrophobic coatings are applied on surfaces such as solar panels and windows. In addition, superhydrophobic coatings can enhance anticorrosion properties by separating water in contact with metal substrates. When coatings are in service, they are prone to damage due to their thin section: once damage occurs, the coatings will lose their functionality such as anticorrosion. Thus, by applying self-healing coatings that can repair themselves is attractive; by self-healing, the coatings will have a longer service life and there is no need to re-apply them when they experience damage.

Polymer Coating Deposition Techniques for Advanced Tribological Applications

Polymer coating deposition on a wide variety of engineering substrates has gained significant attention. Coatings are tailored to provide specific characteristics, such as wear, corrosion, chemical and weathering resistance, to improve thermal conductivity, to provide electrical insulation, and in the case of some polymers, to provide solid lubrication and low friction. Thermal spray (TS) and cold dynamic spray or simply cold spray (CS) are the main techniques employed to coat polymers onto substrates.

Among the main advantages of TS are: (a) the feasibility to coat large components of complex geometries, (b) the use of powder as raw material (eliminating the use of solvents), and (c) the possibility of the technique being applied in the field, to coat and/or repair a component. Depending on the physical principle employed for deposition, TS techniques can be subcategorized as shown in Fig. 1. For instance, in TS, deposited polymer material in powder form adheres to the substrate by a high velocity and high temperature thermal jet produced by electrical or chemical energy. This energy is used to heat, melt, and spray the molten material introduced in the flame through a nozzle, before impacting the target surface. Once the particles impact the substrate, they solidify and form the coating by superposition (Petrovicova and Schadler, 2002).

In CS the amount of energy (electric or calorific) required to accelerate the particles to the substrate is lower, compared to TS. In fact, the name CS refers to the range of temperatures employed during the flow of the gas through the nozzle, which can vary from -100 to 100°C (Raletz *et al.*, 2006). In CS, due to the relatively low temperature process, which is usually lower compared to the melting point of the powder, the adhesion forces between the deposited powder and substrate, along with the cohesion forces between the powder particles in the solid state, make this process remarkable. In fact, due to the low temperature and the absence of oxidation, the final coatings produced by CS not only have lower residual stresses and porosity, but higher bond strength, compared to TS techniques (Champagne and Helfrich, 2014). Unlike TS, CS can be performed at standard pressure, temperature, and humidity, simplifying the operating conditions.

Fig. 1 Thermal spray deposition techniques and subcategories. Modified from Wen, C., 2015. Surface Coating and Modification of Metallic Biomaterials. Woodhead Publishing.

According to **Fig. 1**, TS deposition methods for polymer coatings are classified depending on the energy source employed to accelerate the powder particles towards the substrate. As shown in **Fig. 1**, powder flame spray, arc wire, plasma, high velocity oxyfuel (HVOF), and CS are considered the most popular TS polymer coating deposition techniques, where the final coating thickness ranges from tenths of micrometers to several millimeters (Bach *et al.*, 2006).

Fig. 2(a) shows a schematic of the wire flame spray, where a concentric wire material is driven and reacts with an oxygen-fuel rich gas flame. As a result, the material is melted and sprayed towards the substrate to be coated. Similarly, in powder flame spray, the wire is replaced by a polymer powder which reacts with the flame and reaches the substrate to form the coating. Plasma is another TS process that can be used for the deposition of polymer coatings. As shown in **Fig. 2(b)**, an arc of high frequency develops between a cathode (usually tungsten) and anode, ionizing the gas flowing through the electrodes (for instance He, N₂, H₂). As a result of this process, the temperature of the plasma can reach up to approximately 25,000°C and is used to melt the powder material and accelerate it towards the substrate (Davis, 2001).

Surface preparation is one of the key aspects to avoid delamination of the coating to the substrate. This process is usually performed by roughening the substrate by using grit blasting, which increases the surface roughness. As a result, the exposed surface of the substrate is activated by an increase in free surface energy which improves the bonding between the impacting polymer particles and the substrate (Fender, 1996; Vyawahare, 2006). In CS, powder polymer particles reach and bond to the substrate in solid state by the acceleration of the gas that passes through a convergent-divergent nozzle (Assadi *et al.*, 2011).

Different types of polymers for advanced tribological applications can be applied using the aforementioned techniques. These polymers are classified on a pyramid, based on their mechanical properties, operating temperatures and cost (see **Fig. 3**) (Friedrich, 2018). On top of the pyramid shown in **Fig. 3**, polymers such as Polyetheretherketone (PEEK), Polyimides (PI), Polyamide-imide (PAI), Polytetrafluoroethylene (PTFE) and aromatic thermosetting copolyester (ATSP) (Frich *et al.*, 1996; Frich and Economy, 1997; Zhang, 2008; Lan *et al.*, 2016) are designed for tribological problems, and are commercialized as powders, where their size ranges from 10 to 180 µm (Berretta *et al.*, 2014).

As shown in **Fig. 4**, polymer powder can be obtained using cryogenic mechanical grinding. Tribological studies of high performance thermoplastic polymer coatings, show that flame spray, HVOF, plasma, electrostatic deposition and CS are the most popular techniques to deposit a variety of high-performance polymers (HPPs). For instance, through annealing treatment and holding time of the substrate, it was shown that PEEK coatings deposited on Al substrates by flame spraying showed higher crystallinity. Thus, higher hardness and wear

Fig. 4 SEM microscopy images of PEEK powder (A–D), and (E) polymer powder of Ultra high molecular weight polyethylene (UHMWPE). Modified from Berretta, S., Ghita, O., Evans, K.E., 2014. Morphology of polymeric powders in Laser Sintering (LS): From polyamide to new PEEK powders. European Polymer Journal 59, 218–229.

resistance, compared to those treated with lower annealing temperature (Zhang *et al.*, 2006b). Other studies, also show the benefits of substrate pretreatment by Nd:YAG (*neodymium-doped yttrium aluminum garnet*) and CO₂ infrared lasers; these treatments provide advantages compared to conventional grit blasting, especially for brittle materials. Laser surface pretreatment has the advantage of delivering a significant amount of power on a small area of the work piece, without compromising the bulk properties of the substrate. These pretreatments, also reduce the heating time (compared to flame and induction heating) of the substrate, and improve the mechanical properties of the final coatings (Zhang *et al.*, 2006a). It was proven that treatment with CO₂ laser improved densification of the PEEK coating, leading to less porosity and higher mechanical properties, compared to Nd:YAG laser treatment.

Polymer coating deposition is also carried out using electrostatic spraying, where the polymer powder is electrostatically charged under low current (in the μA range) and voltage (30–90 kV) and applied onto the electrically grounded substrate. There is abundant literature related to tribological studies of HPPs deposited using electrostatic deposition. These studies were mainly focused on deposition of blended PEEK, PI, PTFE, and ATSP polymer powders deposited onto substrates such as gray cast iron, Al390-T6, sintered iron, and Mn-Si brass, which are found in different air-conditioning and refrigeration components, as well as electrical submersible pumps (ESPs) (Shaffer and Rogers, 2007; Demas and Polycarpou, 2008; Dascalescu *et al.*, 2009; Nunez *et al.*, 2010; Nunez *et al.*, 2011; Yeo and Polycarpou, 2012; Lan *et al.*, 2017; Lan *et al.*, 2018; Lan and Polycarpou, 2018; Nunez *et al.*, 2019). Deposition of the aforementioned HPPs as coatings through electrostatic deposition, and tailored for tribological applications has proven to be effective and inexpensive, compared to other techniques. However, deposition techniques, such as CS spray eliminate the curing process, required in the electrostatic technique.

Fig. 5 shows typical cross-sectional images of different polymer coatings obtained by electrostatic deposition. It can be seen that the typical thickness of the coatings is of the order of tenths of microns (Nunez *et al.*, 2011). The list of polymers that can be sprayed onto different substrates using different TS techniques is listed in reference (Petrovicova and Schadler, 2002). There are other techniques such as spin coating and dip coating that can be used for the deposition of uniform thin polymer films (from few nanometers to few micrometers) on different substrate materials, and are used in different sectors, such as the semiconductor and biomedical industries. However, coatings developed using these techniques are not specifically designed to address tribological issues (Danglad-Flores *et al.*, 2018).

Tribology of Polymer Coatings Under Extreme Working Conditions

Increasing demand of advanced materials that can withstand extreme operating conditions in several industries, has called the attention of the polymer industry for the development of composites and blends that can perform well under difficult or extreme working conditions. For instance, spacecrafts and satellites are exposed to cosmic rays, impact of debris from spacecraft and

Fig. 5 Cross sectional SEM images of typical HPP coatings: (a) PEEK/PTFE, (b) PTFE/MoS₂, (c) Fluorocarbon, (d) PEEK/Ceramic deposited on gray cast iron by electrostatic deposition. Modified from Nunez, E.E., Yeo, S.M., Polychronopoulou, K., Polycarpou, A.A., 2011. Tribological study of high bearing blended polymer-based coatings for air-conditioning and refrigeration compressors, *Surface and Coatings Technology* 205 (8–9), 2994–3005.

meteoroids, ultra violet radiation, vacuum, microgravity, thermal cycling, and cryogenic conditions, which make the design and selection of materials for these applications challenging (Pippin, 2003; Kondyurina *et al.*, 2006; Wang *et al.*, 2016; Gao *et al.*, 2018). In the air-conditioning and refrigeration industry there has been interest in oil-less compressors, mainly due to the negative thermodynamic effect from the liquid lubricant/refrigerant mixture in the refrigeration cycle. The mixture not only decreases the thermodynamic efficiency, but under boundary/mixed lubrication conditions, it can affect the properties of the lubricant causing scuffing on the sliding components (Demas *et al.*, 2005; Cannaday and Polycarpou, 2006; Nunez *et al.*, 2008; Akram *et al.*, 2014).

Another industry where harsh operating conditions cause tribological issues, is the oil and gas industry. In this regard in ESPs, high bearing loads and high temperature can cause failure of the lubricant film in the hydrodynamic bearings, causing a transition from hydrodynamic to boundary and mixed lubrication regimes. As a consequence, interactions of the asperities of the pad bearings might cause seizure, leading to scuffing at the bearing contact interface (Wang, 1997; Lan *et al.*, 2017). As stated above, advanced thermoplastic polymers can be used to coat different substrates in the tenths of micrometer thickness. One of the main advantages of high bearing blended polymer coatings, is not only the fact that they can provide solid lubrication in the form of third bodies under unlubricated conditions (in the absence of liquid lubricant), but also the fact that they provide a low cost/efficiency ratio (Yeo and Polycarpou, 2012, 2013).

We have been broadly studying the tribological performance of high bearing load blended polymer coatings based on PEEK, PTFE, and ATSP for different industrial applications; Testing instruments include specialized custom-made tribometers, which are capable to carry out tests at high normal loads (up to 5000 N), high temperatures (from 120 up to 1000°C) and high pressures up to 13.8 MPa (Dascalescu *et al.*, 2009). In the air-conditioning and refrigeration industry the studies have been focused on the replacement of sliding components. Namely, Al390-T6, Mn-Si brass, which are used in automotive swash plate compressors, and gray cast iron, and sintered iron, commonly found in scroll and piston compressors, respectively (Yeo *et al.*, 2010).

Three different commercially available PTFE-based coatings deposited onto gray cast iron disks (Dura-Bar G2); namely, DuPont® 958-303, DuPont® 958-414 and Whitford Xylan® 1052, all of them with thickness of approximately 20–30 µm (see Fig. 6), were tested against 52100 steel, under unlubricated conditions (Demas and Polycarpou, 2008). The first two coatings were PTFE/pyrrolidone based, while the latter was PTFE/MoS₂. These coatings were tested under reciprocating motion ($\pm 30^\circ$ at a frequency of 4.5 Hz) to simulate the contact of the wrist pin and the piston in a piston-type compressor. Under aggressive loading conditions (460 MPa Hertzian line contact pressure), the experimental results show that scuffing at the interface was retarded due to the action of third bodies coming from the wear debris. This debris was kept trapped at the contact interface and retarded scuffing by the action of solid lubrication. This was proved after running experiments at 2, 5, 10, and 60 min, where it was shown that most of the wear took place during the running-in transient period, by comparing wear depth contact profilometry measurements against the thickness of the coatings, being in all cases around 20–30 µm (see Fig. 6). These results proved that advanced polymer coatings could potentially be applied in situations of high contact stresses under unlubricated conditions, being a relatively cheaper solution compared to hard diamond-like carbon (DLC) coatings (Grill, 1993; Donnet and Erdemir, 2004).

Studies were performed to understand the feasibility of applying the aforementioned coatings on Al390-T6, gray cast iron, and sintered iron substrates (Yeo *et al.*, 2010). It was proved through X-ray Photoelectron Spectroscopy (XPS), that Al390-T6 was

Table 1 List of different commercial polymer coatings and engineering substrates

Coating material	Vendor	Substrate material compatibility				Thickness (μm)
		Al390-T6	Gray cast iron	Sintered iron	Chrome copper C182000	
PEEK/PTFE	Southwest Impreglon	Good	Excellent	Excellent	Excellent	30–40
PTFE/MoS ₂ (Fluorolon [®] 325)	Southwest Impreglon	Good	Excellent	Excellent	–	20–30
Fluocarbon (Impreglon [®] 218)	Southwest Impreglon	Poor	–	–	–	20–30
PTFE/Pyrrolidone-1 (DuPont [®] 958–303)	DuPont [®]	Poor	Excellent	Excellent	–	20–30
PTFE/Pyrrolidone-2 (DuPont [®] 958–414)	DuPont [®]	Poor	Excellent	Excellent	–	20–25
PTFE/MoS ₂ (Whitford Xylan [®] 10–52)	Whitford [®]	Excellent	–	Excellent	–	15–20
ATSP/PTFE	ATSP Innovations	–	Excellent	Excellent	Excellent	20–30

difficult to coat and that PTFE/MoS₂ was the only polymer material capable to adhere onto this substrate, and also the only one which did not suffer severe scuffing (Dascalescu *et al.*, 2009). It can be seen in the XPS spectra of Fig. 7(a), that fragmentation of PTFE enabled its interaction with the Al390-T6 substrate. As a result, this chemical interaction improved the adhesion of PTFE to the substrate, based on the C-species peaks at 292 eV, related to PTFE (which is found as a peak in the F1s core level spectra analysis (Fig. 7(b))). It was proven that under unlubricated sliding conditions, these coatings provide solid lubrication through their ability to form transfer films, making them an attractive solution to replace metal tribopairs in oil-less engineering applications (Ovaert and Cheng, 1991; Bahadur, 2000; Nunez and Polycarpou, 2015).

Feasibility of deposition of these commercial coatings onto different engineering substrates is summarized in Table 1. Micromechanical properties of these coatings were also obtained using a TI-950 TriboIndenter (Yeo and Polycarpou, 2013). The elastic modulus and hardness as a function of contact depth is shown in Fig. 8. It can be seen that all coatings show consistent values of reduced elastic modulus (E_r) and hardness (H) at shallow contact depths (1.5–2.0 μm), except for the case of the PEEK/PTFE coating, with its behavior is attributed to significant pile-up. Fig. 9 shows the wear rates of the same coatings under both oscillatory and unidirectional sliding conditions. It can be observed that there are higher wear rates and COF values under oscillatory conditions, compared to unidirectional sliding, for the same polymer coating. This can be explained by the fact that temperature at the sliding interface is governed by the sliding speed and normal load, which is higher under unidirectional sliding, compared to small amplitude oscillatory sliding. It is expected that under high temperature, adhesion and material transfer will be

Fig. 8 (a) Reduced elastic modulus and (b) Hardness vs contact depth for five different commercial polymer coatings. Modified from Yeo, S.M., Polycarpou, A.A., 2013. Micromechanical properties of polymeric coatings. *Tribology International* 60, 198–208.

Fig. 9 Friction coefficient vs. wear rate of different PEEK and PTFE blended polymer coatings in CO_2 (22°C and 0.17 MPa) environment at 445 N normal load under both; unidirectional and dry-oscillatory conditions. enhanced due to higher adhesion which ends up in lower wear rates. Also, under oscillatory conditions, material has to be replenished due to the back and forth sliding motion, decreasing material transfer efficiency (Yeo and Polycarpou, 2014).

Studies on the performance of polymer coatings designed for tilting pad bearings in ESPs have also been performed. C182000 chrome-copper disks were coated by electrostatic deposition with ATSP/PTFE (Zonyl® MP1100) blends (Lan *et al.*, 2017). ATSP-based coatings were compared to PEEK-based coatings (1704 PEEK/PTFE) deposited on the same substrate by an authorized vendor (see Table 1), and both tested against AISI 4130 steel and C932000 bronze cylindrical pins. The experiments were carried out under hydrodynamic lubrication in an abrasive three body (silica) sand (2 wt% silica sand #140) and ISO 46 mineral oil to simulate the conditions of the contaminated lubricated system. The experiments were performed at a nominal contact pressure of 6 MPa with a duration of 30, 80, and 120 min at a sliding speed of 1.9 m/s. It was shown that friction coefficient was lower for PEEK/PTFE coating, compared to ATSP, due to the lower initial roughness of the PEEK/PTFE. Wear rates were lower in case of ATSP tested with smaller sand size, compared to the case of larger #140 sand. This behavior was attributed to the interaction of smaller sand particles at the contact interface when compared to larger size particles (Myshkin *et al.*, 2005). Overall, considering the three different materials tested, ATSP exhibited the lowest wear rate followed by C18200 (chrome-copper), and PEEK/PTFE.

The tribological performance of polymer coatings under cryogenic conditions is of great importance for some industries. For instance, the advent of liquid hydrogen (LH_2) to power rockets and engines poses new challenges in the research of materials that can withstand harsh conditions at very low temperature (Friedrich *et al.*, 2009). The behavior of PTFE at cryogenic temperatures was studied at two different temperatures; namely room temperature (RT) and 77K. It was shown that wear debris of PTFE at RT was governed by creep and shear stresses due to plowing; however, at -196°C abrasion is the main wear mechanisms and wear rate decreases due to an increase in surface hardness (Michael *et al.*, 1991). Tribological performance of ATSP and PEEK based coatings deposited on gray cast iron and tested at -40°C , -100°C and -160°C using a specialized tribometer at normal loads of 5 and 10 N was investigated. No measurable wear was obtained after testing of ATSP and PEEK, and the COF was higher in the PEEK material tested at different cryogenic experimental temperatures. Also, after testing, cracks were observed on the wear tracks and they were related to the elastic modulus of the polymer coatings, where a more ductile PEEK was easier to plastically deform resulting in less microscopic cracks, compared to ATSP.

Hydrophobic Coatings and Their Applications

When a water droplet contacts with a rough solid surface, a contact angle (CA) forms, which is the angle that forms with the vertex located at the three-phase (liquid–vapor–solid) common point: one arm is the liquid–solid interface and the other arm is the liquid–vapor interface, as shown in Fig. 10. When the CA is smaller than 90° , as shown in Fig. 10(a), the solid surface is a hydrophilic surface, which means the solid surface has high surface energy and is able to attract water and wet the surface. Fig. 10(b) shows a hydrophobic surface that has a CA larger than 90° ; the hydrophobic surface has a low surface energy and repels water and resists wetting. When the CA is larger than 150° , the surface is called superhydrophobic surface. The CAs denoted in Fig. 10(a) and (b) are in static condition; once the droplet is in dynamic condition, the contact angle is in a range between receding contact angle (θ_r) and advancing contact angle (θ_a), as shown in Fig. 10(c) on a tilting surface. The contact angle hysteresis (CAH) is equal to the advancing contact angle (θ_a) minus the receding contact angle (θ_r). When the adhesion between the solid and liquid is low, the CAH is small, and vice versa. Thus, the CAH is an important parameter characterizing adhesion, wetting, and energy dissipation during droplet flow (Nosonovsky and Ramachandran, 2015).

The lotus leaf is well-known for its superhydrophobic and self-cleaning property. Fig. 11 shows three different magnifications of SEM images of a lotus leaf surface. Fig. 11(a) with the lowest magnification shows the surface microstructure, which is formed by papillose epidermal cells. After zoom in, a fluffy structure covering the micro-size cell is revealed, as in Fig. 11(b). With further zoom in, the fluffy structure is revealed and shows nano epicuticular wax tubules, as in Fig. 11(c) (Koch *et al.*, 2009). Surfaces with non-polar or less polar material have low surface energy, and such materials include hydrocarbon components of epicuticular waxes. For the lotus leaf, with the nano epicuticular wax tubules as in Fig. 11(c), air is enclosed in the nano structure and forms an

Fig. 10 Presentation of contact angles: (a) Hydrophilic surface, contact angle (CA) $< 90^\circ$, (b) hydrophobic surface, $\text{CA} > 90^\circ$, (c) on a tilting surface, contact angle hysteresis (CAH) = advancing contact angle (θ_a) – receding contact angle (θ_r).

Fig. 11 SEM micrographs with three magnifications on Lotus leaf surface, which consists of a microstructure formed by papillose epidermal cells covered with epicuticular wax tubules on the surface, which create nanostructures. Modified from Koch, K., Bhushan, B., Jung, Y.C., Barthlott, W., 2009. Fabrication of artificial Lotus leaves and significance of hierarchical structure for superhydrophobicity and low adhesion. *Soft Matter* 5 (7), 1386–1393.

air nano tubule composite surface. This composite surface results in low surface energy by increasing the water/air interface and decreasing the solid/water interface.

With large CA, the water is hard to wet the surface and the water droplet forms a near spherical geometry (Barthlott and Neinhuis, 1997). Dirt particles resting on the lotus leaf are usually larger than the surface microstructures, which means that the real solid-solid contact area is small and the adhesion force is also small. Thus, the particle material is more readily wetted by water compared to the epicuticular wax. When the particles encounter the rolling water droplet, the particles are ready to be absorbed by the water droplet and be detached and removed from the lotus leaf (Barthlott and Neinhuis, 1997). Inspired by the micro/nano structure of lotus leaf, artificial coatings have been developed to possess functions such as self-cleaning (Nine *et al.*, 2015; Fenero *et al.*, 2017; Selim *et al.*, 2017; Xiao *et al.*, 2017; Selim *et al.*, 2018b), enhanced antifouling (Selim *et al.*, 2017; Selim *et al.*, 2018a,b), fluid drag reduction (Dong *et al.*, 2013; Srinivasan *et al.*, 2015), and deicing (Arianpour *et al.*, 2016; Nazhipkyzy *et al.*, 2016; Nine *et al.*, 2017). A common method to produce artificial hydrophobic coatings is to use polymers as a binding agent and add different micro/nano particle materials to form the micro/nano structured surfaces (Nine *et al.*, 2015; Fenero *et al.*, 2017; Selim *et al.*, 2017; Xiao *et al.*, 2017; Selim *et al.*, 2018b).

For self-cleaning, the CA should be large, the CAH should be small, and the surface should be formed by a non-polar material. In addition, the hydrophobic coating should have good abrasion/scratch resistance to ensure good durability (Nine *et al.*, 2015), and antistatic capability to dissipate static electricity (as static electricity is prone to absorb small dirt particles (Fenero *et al.*, 2017)). To maintain superhydrophobicity, the key is to maintain the micro/nanostructure, and this could be accomplished using a high wear resistance material, or by wear of the surface layer, but exposing new nanostructure underneath. Nine *et al.* (2005) designed graphene-based superhydrophobic composite coatings with robust mechanical strength, and their tests showed that superhydrophobicity was retained even after sandpaper abrasion and crosscut scratching. In another study, by using a high scratch resistance oxide La_2O_3 , Xiao *et al.* (2017) synthesized coatings that maintained their nanostructure and superhydrophobicity after 80 cycles of sand abrasive sliding. Another terminology worth mentioning is omniphobicity, which describes a surface that has repellent property for both polar and non-polar liquids (such as water, oil, methanol, octane, crude oil and blood), enabling the so called “full self-cleaning” characteristics (Tuteja *et al.*, 2008; Wong *et al.*, 2011; Fenero *et al.*, 2017). These omniphobic surfaces could be used for biomedical fluid handling, fuel transport, self-cleaning windows and optical devices (Wong *et al.*, 2011).

After immersion in seawater, ships will have biofouling on their hulls, thus will increase the fluid drag and fuel consumption (Selim *et al.*, 2018b). Fouling release agents such as Ag nanoparticles, copper and/or booster biocides are commonly used in antifouling paints. When antifouling paints are produced into hydrophobic surfaces, the antifouling performance can be effectively enhanced by inhibiting fouling adhesion and the self-cleaning properties (Selim *et al.*, 2017; Selim *et al.*, 2018a,b). In addition, as water can easily move on hydrophobic surfaces, it can decrease the shear force between the water and the surface (Srinivasan *et al.*, 2015). Dong *et al.* (2013) studied the drag difference between a normal surface and a hydrodynamic surface, and they found that the superhydrophobic surface with static CA of 159.7° could reduce the drag force up to 49.1%, compared with the normal surface. Thus, applying antifouling coatings with hydrophobic surfaces would have combined benefits of enhanced antifouling and hydrodynamic drag reduction.

Another useful application for hydrophobic coatings is for deicing. Ice formed on a surface is due to surface adhesion that retains the water droplets. Hydrophobic surfaces can repel water and have low adhesion, and this can delay the formation of ice and ease the mechanical ice removal (Nazhipkyzy *et al.*, 2016). In addition, for self-induced deicing on a surface, ice removal usually starts when solid-ice melts into water at the interface; while water is super slick on the hydrophobic surface, thus enabling excellent deicing performance (Nine *et al.*, 2017).

Self-Healing Coatings and Their Applications

Polymer coatings are attractive due to their cost effective and excellent performance in different applications. However, when used in actual environments, such as for solar panel protection, the polymer coatings could be eroded or scratched by the high speed abrasive sand particles in the wind (Humood *et al.*, 2017). In addition, the coatings may suffer from decomposition under sunlight (Mozumder *et al.*, 2019). When coatings on solar panels suffer from such damages, transmittance and wettability will decline. Therefore, expensive and inconvenient interval renovations of the coatings is necessary (Mozumder *et al.*, 2019). Inspired by natural plants, such as the lotus leaf that can repair its surface superhydrophobicity, even after damage by regrow of epicuticular wax tubules on the surface (Neinhuis *et al.*, 2001), researchers have shown interest on coatings with self-healing capability, which would be cost-effective and efficient in actual applications (Mozumder *et al.*, 2019). Specifically, anticorrosion has been one of most attractive applications for self-healing coatings (Cho *et al.*, 2009; Samadzadeh *et al.*, 2010; Yabuki and Okumura, 2012; Schreiner *et al.*, 2017; Guo *et al.*, 2018; Njoku *et al.*, 2018).

Maintaining the functions of the coating is the main goal of self-healing, and there are mainly two different methods, namely physical and chemical methods, to achieve this goal. Physical self-healing does not involve any chemical reactions. For example, Wong *et al.* (2011) designed an omniphobic liquid film by using the nano/microstructured substrates to lock in place the infused lubricating fluid: Because the liquid surface is intrinsically smooth and defect-free, the surrounding liquid can immediately wick into the scratched area and the surface is self-healed. In another example, Golovin *et al.* fabricated a superhydrophobic coating that can maintain its hydrophobicity by expositing new micro structures after abrasion. In addition, the coating can regain its surface texture by immersing in heat even after 150 MPa pressure compression (Golovin *et al.*, 2017). In the third example, Yabuki, *et al.* mixed a

Fig. 12 Schematic of self-healing process, (a) Self-healing coating containing microencapsulated catalyst (yellow) and phase-separated healing agent droplets (blue) in the coating, (b) Damage to the coating layer releases catalyst (green) and healing agent (blue). (c) Mixing of healing agent and catalyst in the damaged region, (d) Damage healed by cross-linked PDMS, protecting the substrate from the environment. Modified from Cho, S.H., White, S.R., Braun, P.V., 2009. Self-healing polymer coatings. *Advanced Materials* 21 (6), 645–649.

superabsorbent polymer (SAP) additive in the vinyl-ester polymer to coat on a metal substrate for corrosion protection. After scratch damage, the SAP in the composite coating could absorb water and the swelled SAP can prevent the diffusion of dissolved oxygen to reach the metal substrate and thus inhibits corrosion (Yabuki and Okumura, 2012; Yabuki *et al.*, 2018).

Compared to physical self-healing, chemical self-healing is more active. Cho *et al.* used a self-healing chemistry based on di-*n*-butyltin dilaurate catalyzed polycondensation of polydimethylsiloxane (PDMS) and polydiethoxysiloxane (PDES). As shown in Fig. 12(a), the dimethyldiethoxysilane (DMDNT) catalyst is microencapsulated and the PDMS-based healing agent (a mixture of 96 vol% HOPDMS and 4 vol% PDES) is distributed evenly as droplets on the coating outside of the microencapsulates. When the coating is damaged by scratch, as in Fig. 12(b), the microencapsulates will break, the catalyst can flow to the scratch and contact with the healing agent. Once the catalyst mixes with the healing agent, as in Fig. 12(c), they will react with each other and heal the scratch and protect the substrate from the environment (Fig. 12(d)). In the same study, Cho *et al.* produced another self-healing coating by encapsulation of both the catalyst and the healing agent, which provided better corrosion protection, compared with the one shown in Fig. 12(a).

There are different chemistries that can be used for self-healing coatings. Lu *et al.* showed that fabrication of composite material coatings with a healing agent could be a promising strategy which was effective, low-cost and easily scalable (Zhai *et al.*, 2018; Zhou *et al.*, 2018). According to Hillewaere and Du Prez (2015), to achieve better healing efficiency, the self-healing chemistry needs to be accommodated with the coating matrix: for siloxane and azide-alkyne chemistry, they work well only in PDMS and polyisobutylene (PIB) matrix. To get a better mixture and cover over the damaged area, reducing the viscosity of the healing chemistry by adding a solvent improves the recovery. There are many different ways to produce the microcapsules for healing chemistry (Park and Braun, 2010; Najjar *et al.*, 2018; Njoku *et al.*, 2018; Zhang *et al.*, 2018). For example, Zhang *et al.* (2018) produced Poly(urea-formaldehyde)-epoxy ester microcapsules through a two-step process in an oil-in-water emulsion: a shell pre-polymer solution was formed in the first step; in the second step, the epoxy was added in the solution and then agitated to an emulsion status, then by changing the temperature and PH, the pre-polymer will consolidate on the surface of the ester droplets and form the ester microcapsules.

In another work, Park and Braun (2010) applied a coaxial electrospinning method to form the capsule for self-healing chemistry and this is a purely physical approach to form the core/sheath structure. As shown in Fig. 13(a) depicting the schematic for the coaxial electrospinning system, two viscous liquids, namely the shell polymer and healing agents (two-part healing agent system), are feed through the inner and outer capillaries, respectively. By controlling the feeding liquids and other operational conditions, the healing agents can be encapsulated in the beads along with polymer nanofibers, as shown in Fig. 13(b) of the randomly orientated core-shell bead-on-string morphology, with two different healing agents in the bead and string shell. After the deposition of the electrospun fiber mat, a UV curing resin was sup-cast on the fiber mat and then cured as self-healing coating. Fig. 13(c) shows the control and self-healing coating samples after initial scratch and aging in corrosion environments, which clearly prove the effectiveness of the healing performance (Park and Braun, 2010).

Fig. 13 Coaxial electrospinning of self-healing coating system, (a) the coaxial electrospinneret and fiber spinning process, (b) SEM image of as-spun core-shell bead-on-string morphology, (c) Photographs of control and self-healing coating samples that were stored under ambient conditions for 2 months after 5 days salt water immersion. Modified from Park, J.H., Braun, P.V., 2010. Coaxial electrospinning of self-healing coatings. *Advanced Materials* 22 (4), 496–499.

Fig. 14 HNT Nanocontainer for anticorrosion agent, (a) SEM image of HNT, (b) TEM image of HNT, (c) Process of loading and coating of HNT. Modified from Dong, C., Zhang, M., Xiang, T., *et al.*, 2018. Novel self-healing anticorrosion coating based on L-valine and MBT-loaded halloysite nanotubes. *Journal of Materials Science* 53 (10), 7793–7808.

The above mentioned chemical self-healing methods are based on repairing the coating by chemical reaction of the healing agents and forming a new layer on the damaged area. Rather than using the healing agents' reaction, another chemical self-healing method is the continually releasing of functional chemicals, such as anticorrosion agents, in the damaged area where no protection can be supplied by the physical coating coverage. To extend the service life after damage, the functional chemicals need to be released gradually from the carriers, such as halloysite nanotubes (HNT) (Zahidah *et al.*, 2017), cellulose nanofibers (Yabuki *et al.*, 2016) and polymer core-shell nanocontainers (Li *et al.*, 2014). HNT material is abundantly available in nature and it can significantly extend the release time of an anticorrosion agent in water (Zahidah *et al.*, 2017). As shown in Fig. 14(a) and (b) of the HNT morphology, the anticorrosion agent is able to stay in the hollow nanotubes. Fig. 14(c) shows the loading and coating process for HNT.

Under vacuum, the mixture of HNT and the anticorrosion agent was stirred and thus the agent was loaded in the nanotubes. In the next two steps, the loaded HNT was coated with double polyelectrolyte, namely Poly(allylaminehydrochloride) (PAH) and poly(styrene sulfonate) (PSS), respectively. When used in coating applications, the PAH and PSS films can form porous structures and then gradually release the anticorrosion agent from HNT to protect the metal substrate (Dong *et al.*, 2018). Rather than load the anticorrosion agent in side hollow nanotubes, Yabuki *et al.* coated corrosion inhibitors on the surface of the cellulose nanofibers, then the coated nanofibers were mixed with a base polymer and then deposited on the metal surface (Yabuki *et al.*, 2014; Yabuki *et al.*, 2016). When scratch occurs, the corrosion inhibitor is gradually released along the nanofibers pathway, thus protecting the substrate (Yabuki *et al.*, 2014). In addition, by changing the PH value of the coating, the release speed of corrosion inhibitor can be controlled (Yabuki *et al.*, 2016).

Conclusions

In this article, different advanced polymeric coatings and their applications were reviewed, and the following conclusions could be drawn:

- (1) High bearing blended polymer coatings based on PEEK, PTFE, and ATSP materials show promising tribological behavior under aggressive contact conditions. Even in the absent of liquid lubrication, in applications such as air-conditioning and refrigeration compressors, electrical submersible pumps, and under cryogenic conditions, they proved their suitability to withstand demanding contact and sliding conditions at the interface, while maintaining friction and wear at acceptable levels;
- (2) One of the key aspects in the performance of high bearing blended polymer coatings is their ability to provide self-lubricity at the contact interface, by trapping wear debris or third bodies at the contact interface. Keeping these third bodies is what avoids/retards scuffing adhesive phenomena under stringent sliding conditions;
- (3) Electrostatic deposition is one of the most cost/effective methods to coat metallic engineering substrates with polymer coatings. Compared to techniques such as thermal spray, electrostatically deposited coatings proved to perform well under aggressive conditions; and
- (4) Both superhydrophobic and self-healing coatings using special chemistry and structure are used to fulfil their desired properties. Both coatings are using green technologies that can reduce labor cost and reduce environmental impact to maintain the coatings' functionality. Superhydrophobic coatings are more attractive for self-cleaning applications and self-healing coatings are more attractive for anticorrosion applications.

Introduction

An ever-increasing growth in economic development, associated products, and services is resulting in improved living standards. These developments, accompanied by massive population growth are increasing the demand for World's non-renewable resources. The transport sector alone consumes more than half of the global oil production. The number of vehicles is expected to increase to 1.7 billion in 2035 which is almost two times more than what is currently being used (IEA, 2012). This scenario can cause a severe scarcity of non-renewable fossil fuels in the near future that may lead the modern economy to experience an enormous challenge to tackle the energy security and associated socio-economic challenges. This may also create barrier to sustainable developments that are necessary to meet the current demands without hampering the ability of the next generations to fulfil their needs. Automobiles are also considered as the major emitters of toxic gases that cause lung diseases, cancers and respiratory problems. Alternative fuels are not only considered to mitigate environmental burden but also to enhance the energy security, create jobs locally and improve income level of particular region (Macombe *et al.*, 2013). Given these economic, social and environmental significances, there is an urgent need to look into alternative transport fuels.

Implementation of renewable energy alternatives and possible energy efficiency and energy conservation strategies are the key pathways to address future sustainable energy challenges. However, the environmental, economic and social implications need to be assessed before implementing any such initiatives which is known as 'triple bottom line' or TBL analysis (Hall, 2011). The LCSA approach evaluates TBL objectives effectively over the life cycle of a product/service (Santoyo-Castelazo and Azapagic, 2014). Under the guidelines of United Nation Environmental Programme (UNEP) and the Society of Environmental Toxicity and Chemistry (SETAC), LCSA comprises of ELCA, LCC and SLCA under the identical system boundaries (UNEP, 2011).

Fig. 1 shows the standard framework that is used to assess the environmental impact of a product or service. It comprises of four stages including goal and scope definition, life cycle inventory, impact assessment and interpretation of results. The first step is to define the goal and scope of the study including the number of stages, processes and the type of inputs and outputs involved. A functional unit is needed to work out the amount of inputs and outputs for developing the life cycle inventory. Once the inventory has been developed, the relevant impact assessment methods are employed to estimate the impacts. Finally, the results are analysed to identify the hotspots, and recommendations are made for improvement in the interpretation phase of the study. The SLCA and LCC can then be conducted using the same system boundary.

The literature shows that a wide range of studies have been conducted on ELCA and LCC of different products and services, whereas the SLCA appears to be a relatively emerging area of attention of researchers. This research reviews the existing literature on alternatives fuels for road vehicles, discuss the methodological aspects and procedures. The study also highlights the lessons learnt, and identifies the avenues for future research. Most of the research on the sustainability aspects of alternative fuels mainly consider the employment of ELCA to assess fuels like bio-liquid fuels, electric vehicles and hydrogen fuel cell (Carneiro *et al.*, 2017; Hawkins *et al.*, 2012; Larson, 2006; McManus *et al.*, 2015; Nordelöf *et al.*, 2014; Shonnard *et al.*, 2015). The purpose of this review,

Fig. 1 Four steps of life cycle assessments. Reproduced from ISO14040, 2006. Environmental management – life cycle assessment – principles and framework ISO.

however, is to study the potential for incorporating all the three elements of sustainability, including ELCA, SLCA, and LCC with particular emphasis on sustainable transportation fuel assessment.

Inclusion of Literature and Review Approach

Seventy seven case studies those were published in the last five years pertaining to LCA of alternative transport fuels are selected from different geographical locations to present the state of the art of the application of LCA for environmental, economic and social sustainability analyses. Following Denham *et al.* (2015), the literature of life cycle analysis of alternative transport fuels has been obtained through keywords from various scientific publishers such as Elsevier Science Direct, Springerlink, Wiley Interscience and Emerald Insight. Key words used for literature searching were: “Alternative fuels”, “Sustainability assessment”, ‘Life cycle assessment’, “Environmental life cycle assessment”; “Life cycle costing”, “Social life cycle assessment” and “Life cycle sustainability assessment”.

Once articles have been gathered, they have been classified to facilitate the reviewing process. The distribution of different types of LCA articles shows that the majority of the studies (62%) only performed environmental life cycle analysis (Fig. 2), and nineteen studies (25%) are comparatively recent and considered ELCA and LCC analyses together. About 50% of these were published over the last 2 years and mainly dealt with an emerging concept of life cycle management (LCM) for assessing alternative fuels. LCM mainly assesses the economic and environmental objectives of sustainable production and consumption of products and services utilizing life cycle thinking approach (Jensen and Remmen, 2006) (e.g., Light Emitting Diode lamps not only reduces energy consumption and environment degradation but also offers long-term economic benefits). Social LCA as well as the integration of triple bottom-line objectives into sustainability assessment are still in infancy. A limited number of articles presented the integration of triple bottom line objectives (5%), but the indicators of these studies have not been adequately developed to measure the TBL pillars. Most of these studies did not consider full life cycle of fuel (For example, all stakeholders throughout the supply chain were not considered in the SLCA and for ELCA and LCC of fuels). As of now, mainly biodiesels, ethanol, CNG, electricity and hydrogen fuel cells have been widely considered as alternative fuel options for road vehicles and so the literature on these fuels have been reviewed.

Except case studies, review articles related to LCA of alternative transport fuels have also been reviewed to know the extent of review performed. Other than refereed journal articles, various reports, books and guidelines on LCA such as LCA hand book, ISO guide line for LCA, UNEP-SETAC LCA guideline and ILCD (international life cycle data) hand book have also been reviewed. Similar sustainability assessment articles on other products and services that were published in journals and conference proceedings and other refereed and credible documents have also been reviewed for comparative analysis, learning experiences and supporting statements in order to find out the research gaps in transportation fuels research. In a nut shell, the review covers all the triple bottom line assessment tools including ELCA, LCC and SLCA for assessing sustainability of alternative transportation fuels to determine the gap of existing research that can assist in the development of sustainable alternative fuel scenarios.

Environmental Life Cycle Assessments (ELCA)

Environmental life cycle analysis is a well-established technique to analyse a product from its cradle to grave and to reveal the hotspots so that more sustainable products/services can be designed. Whilst the first formal guideline of LCA was initially devised by the SETAC in 1993, ISO14040 (2006) and ISO 14044 (2006) published the comprehensive LCA principles and requirements

Fig. 2 Number of articles from different LCA.

which were internationally accepted due to their systematic assessment procedure. Besides, life cycle assessment handbook (Curran, 2012) and ILCD hand book published by European Commission are two other established documents for LCA practitioners to maintain quality and consistency in LCA analysis.

The review found two types of ELCA such as Attributional LCA and Consequential LCA, where the former considers the direct impact linked to fuel in its pathway and has been employed by most of the studies whereas relatively less number of studies considered the latter types which considers indirect effects (e.g., environmental consequences associated with the displacement of existing market items due to introduction of a new product or services) as well as direct. Each of these ELCA can either be process based or economic input output LCA (EIOLCA). Quite limited number of authors (4% among the reviewed articles) considered the EIOLCA as this method is based on only a particular economy and number of indicators to assess a product is not sufficient as well (EIOLCA, 2017). Process based LCA, however, considers direct environmental impacts from input output flows from the production stages of any products and which is usually employed by LCA practitioner around the world.

Though LCA is a well-established technique, but outcome of LCA in some cases was uncertain due to different types of assumptions and data variability. Selection of functional unit (FU), system boundary, allocation strategies, emission databases and impact assessment methods have a great influence on LCA outcomes (Hunkeler, 2014). Selection of an appropriate FU, for example, is quite crucial as all the inputs and outputs for LCA analysis are based on this unit (i.e. if vehicle kilometre or VKT is the functional unit then all the inputs and output for LCA analysis will be based on per vehicle kilometre) and different FUs would produce different results (Reap *et al.*, 2008). This FU is often dependent on client's choice and research questions. Among the selected 71 LCA articles on transportation fuel LCAs, VKT (46%) was the most preferred functional unit, followed by energy content in fuel (MJ, 21%) and the amount of biofuel production (litres, 19%). Few articles (7%), however, did not mention FU explicitly as their data was based on a particular software database and showed either percentage of energy consumption and greenhouse gas (GHG) emission compared to fossil fuel or matrix based study. It is, however, required by the ISO guideline that FU should be consistent and clear within the scope of the study to fulfill the desired objectives. Selection of FU and goal of the study determines the system boundary for a particular product which defines the processes or steps those are required for inclusion in the LCA analysis. Reason for choosing or avoiding any processes are also required to be mentioned clearly so that the results of one study are comparable to the other similar studies. Consideration of different life cycle boundaries for ELCA of alternative fuels are presented in Table 1. Among the reviewed articles only 25% have been found to incorporate vehicle life cycle into the fuel LCA (well to wheel approach) to assess the environmental impacts of fuels. A significant number of studies (35%) considered fuel production only (i.e. upstream stages) in order to capture the hydro-geological variation in fuel production and use in different geographical locations (e.g., emissions and farming practices for biofuel crop production varies with soil and climate) (Tabatabaie and Murthy, 2017). ELCA results vary with system boundaries, and therefore, it is important to consider the same boundary for a comparative analysis of alternative fuels.

Co-product allocation has been found to be necessary to define within a system boundary when there are more than one outputs from a single input. Most of the biofuel production systems have a number of by-products, which have economic value and therefore, the environmental burden in these cases need to be shared by both products and by-products. ELCA results sometimes can vary up to 200% only due to the use different allocation methods (Zhao *et al.*, 2016). Surprisingly, allocation methods were not reported in a number of articles (i.e. 31% of the reviewed articles) while they dealt with both products and by-products (e.g., the animal feed was produced as by-product in liquid biofuel production). It is recommended by ISO that the co-product allocation can be avoided by using either subdivision (division of one process into two more sub processes and collection of the input-output data from an appropriate sub process as conducted) or system expansion (expansion of product systems to include the additional functions related to the co-products). When possible, different allocation methods (e.g., mass, energy and economic allocation) could be employed for comparisons among the results. Finally, LCA practitioners need to think critically for the appropriate allocation method for a particular situation as there is no consensus to use exact allocation methods for LCA till now.

The choice of appropriate impact assessment method has been observed as an important criteria for conducting LCA analysis, as LCA results sometimes vary quite significantly due to the different impact assessment methods and also using different databases. For example, there are no common agreement between the software companies about the emission factors in terms of biogenic carbon dioxide emissions (Fan *et al.*, 2012). The use of different emission factors by different software would give

Table 1 System boundaries considered in ELCA

<i>System boundary</i>	<i>Number of studies</i>
Fuel production + Use in vehicle + Vehicle life cycle	25%
Fuel production + Use in vehicle	30%
Only fuel production	35%
Use in vehicle + Vehicle life cycle	5%
Not mention clearly	5%

different environmental performances for the same product (i.e. fuel in this case) or services (i.e. electricity from alternative fuel). It was thus proposed that local databases are generated for software to reflect the local situation. For example, the emission factor for electricity in Denmark would be different to Australia due to differences in the energy mix. There are some countries that have their well-established databases such as European database, National Renewable Energy Laboratory: US life cycle database, Australian LCI database etc. Besides, different countries should have their own impact assessment methods as the impacts caused in Australia would not be the same as North America or Europe.

Due to these reasons discussed above, it is quite challenging to compare LCA results among themselves. Despite these inherent issues, LCA can make researchers critical thinkers and can potentially act as a decision making tool where there is a range of variabilities associated with the production of products such as biofuels. For example, biodiesel is a renewable energy but it does not mean that it can always be environmentally friendly as it depends on where the feedstock of biodiesel was grown and what was used for producing these fuels. [Tabatabaie and Murthy \(2017\)](#), for instance, showed that global warming potential (GWP) emission for 1 MJ of camellia biodiesel in four locations in northwest USA were varied from 44.33 ± 7 g CO₂-eq to $78.88 \pm 4\%$ g CO₂-eq due to the different production practices, use of different agro chemicals and local weather variations. Among the environmental impact categories, it has been found that GWP was one of the most commonly evaluated indicators for fuel LCAs, because there is an urgent need for choosing alternative fuel(s) in order to reduce the GHG emission from the combustion of fossil fuels ([Shonnard et al., 2015](#)). GWP is actually a measure of how much global warming can be caused over a given period by a given mass of chemical relative to similar mass of carbon dioxide ([Demirel, 2014](#)). All the activities related to alternative fuel production have its own GWP due to the production of GHG emissions. [Biswas et al. \(2011\)](#), for example, showed that the total GWP of canola based biodiesel was 1.1 to 2.1 times lower than conventional diesel.

Variation in global warming potential (GWP) were found to be more significant when land use change was considered during the calculation of LCA due to the lack of methodological standards and practical difficulties on assessment of land use change ([Carneiro et al., 2017](#)). As shown in the [Fig. 3](#), significant difference of results has been observed even for a certain feedstock within a particular country.

Variation of results were also observed for electric vehicle (EV) and fuel cell vehicle (FCV) even in a different states within country due to the variation in electricity mix ([Requia et al., 2017](#)). ELCA has potentially been used for designing an environmentally friendly product first by identifying the 'hotspots' and then by incorporating an environmental mitigation strategy to treat this hotspot. As like previous example, electricity has been identified as an input of the electric vehicle causing the significant impact. Therefore, EV and FCV will be considered as a zero or low carbon vehicles if they are powered by renewable energy sources like wind and solar. ELCA studies also confirm that biodiesel and ethanol are not completely emission free unless the emissions from pre farm (i.e. input or fertilizer production) and on-farm stages (i.e. emissions from soil) are considerably reduced. [Daylan and Ciliz \(2016\)](#), for example, found that ethanol could reduce GWP from 4.3% to 47% but increase the eutrophication, photochemical oxidation potential (POCP) and acidification in one km driving compare to conventional gasoline. Similarly, [González-García et al. \(2013\)](#) in Spain found that biodiesel from rapeseed could reduce 74% GWP and 44% ozone depletion potential (ODP) but increase acidification (59%), eutrophication (214%) and photochemical smog (119%). Sustainable production of bio-liquid fuels with renewable sources, however, can outperform fossil fuels from every aspect, where soil emissions from urea application is low ([González-García et al., 2013](#)).

Though a significant number of studies have already been accomplished on ELCA but still there is a potential research gap in regional basis as LCA results of one place cannot be replicated in other places due to the region specific condition and variability of data ([Tabatabaie and Murthy, 2017](#)). The difference in geographical locations, electricity mix and the climatic condition can cause huge variabilities of results. Countries like USA, Australia and Canada cannot also use the result of one state for the biofuels produced in another state due to these reasons. [Requia et al. \(2017\)](#), for example, studied that life cycle CO₂ emission of plug in hybrid electric vehicle (PHEV) in different cities in Canada ([Fig. 4](#)) were different due to the different electricity mixes and the differences associated with the consumption of different percentage of electricity and liquid fuel during the fuel life cycle. [Fig. 4](#) also shows that the life cycle CO₂ emission varied more than 100% in different cities even within the country and so analysis should be done regionally utilising local databases in order to achieve quality LCA outputs. There are no internationally recognised consensus on the use of impact assessment methods, functional units and impact categories ([Hunkeler, 2014](#)). An agreement at an international level and interactions between the practitioners are some important considerations to overcome these limitations. Besides, both base case and other possible scenario analysis should be done so that readers and policy makers can obtain a wide spectrum of ideas to implement. A range of possible region specific impact categories should also be chosen to justify the goal and scope and if required more than one impact assessment method can be chosen to assess the impact categories ([Cavalett et al., 2013](#)). Region wise databases, best practice guideline (e.g., Australian best practice guideline for life cycle impact assessment) for a particular region are also essential for more informed choices.

Life Cycle Cost Analysis (LCC)

Life cycle cost analysis is quite necessary to know the exact cost associated with a particular product or service over its whole life cycle. The LCC for alternative transport fuels have been performed by the combination of fuel cost and life cycle cost of vehicle as only fuel cost does not reflect the overall economic performance (Sharma and Strezov, 2017). Total life cycle cost, cost/km of vehicle, total cost of ownership (TCO) are the major indicators calculated under LCC where initial cost of vehicle; fuel cost over the life of vehicle; operation and maintenance cost and end of life cost of vehicle were normally considered.

Similar to ELCA impacts, there are also significant amount of variation in findings for LCC in the literature which is obviously due to the difference in underlying assumptions and considerations in different studies. In most of the cases, authors found that the cost of alternative fuel vehicle were higher than the conventional vehicle. In Australia for example, it has been estimated that the TCO of hybrid diesel-electric bus was around 10% higher than the conventional diesel. It has also been expressed that the market penetration of hybrid and hydrogen technology is significantly low compared to conventional diesel fuel and it would be comparable only if diesel price increases substantially (Ally and Pryor, 2016). Similarly, Lajunen and Lipman (2016) in USA found that EV was not cost effective due to the high cost of battery and this is the same for FCV due to expensive hydrogen production and storage systems. Zhou *et al.* (2017) in Canada also came up with almost similar results. Whilst E 10 (10% ethanol with 90% petrol) and B 10 (10% biodiesel and 90% diesel) are successfully implemented in all over the world, though high cost of biofuel production and unfavourable government policies (e.g., subsidized fossil fuel and no subsidy on biofuel) in some countries hinders its cost-competitiveness. Mu *et al.* (2017) also revealed that the cost of biodiesel production from algae would be around 15–20 USD per gallon which was much higher than diesel due to diseconomy of scale.

In contrast to these findings, in a recent study in Florida, USA reveals that the electric trucks have been found to outperform all other existing trucks due to their lower maintenance and repairing cost (Sen *et al.*, 2017). It also has been documented that the use of E 85 instead of petrol could reduce 23% of the life cycle cost in Turkey according to the fuel price of 2009 because of the existence of government subsidy and lower production cost of ethanol in Turkey (Daylan and Ciliz, 2016). Almost similar findings have been revealed by Luo *et al.* (2009) in Brazil. Also Campbell *et al.* (2011) found that biodiesel from algae could be cost competitive with the high rate of production, government subsidy and minimum use of resources (electricity can be produced from the algal by-product and instead of fresh water, salt or waste water, can be used).

Like ELCA, a significant research gap still exists in LCC in terms of regional variation perspective as agriculture, production and transportation cost of fuel are different in different regions. Even cost of petrol and diesel are subsidized in many countries. A systematic regional based LCC study can identify the hotspots and formulate policy instrumentation for reducing the cost. [Ally and Pryor \(2016\)](#), for example, conducted LCC of hydrogen fuel cell vehicle (HFCV) in Western Australian region and summarized that a large scale water electrolysis plant using excess off peak electricity could offer economically feasible option for the HFCV in the state. Besides, cost of relative powertrain along with their maintenance and repairing costs have to be considered in the calculation of life cycle cost of fuels to determine the actual impact but that was not the case in most of the studies due to consideration of biofuel production stages only. Moreover, consideration of inflation and discount rates, government subsidies and proper scenario analysis by considering future cases are essential for proper policy formulations. Moreover, indirect associated cost like environmental emission cost, cost of health impact can be included with LCC in future to address the market failure of these externalities.

Social LCA (SLCA)

Potential social impacts of products or services over their life cycle that are linked to the various stakeholders are considered under SLCA. This is a relatively new LCA guideline that was introduced by United Nation Environmental Programme (UNEP) and Society of Environmental Toxicity and chemistry (SETAC) in 2009 and then further expanded in 2011 ([UNEP, 2009, 2011](#)). Like E-LCA, it also consists of 4 steps for conducting social impact assessment, including goal and scope, life cycle inventory, impact assessment and interpretation of results. However, some modifications and adaptations for SLCA are required as SLCA works with attributes of information or characteristics of a process which cannot be expressed as a unit process. The additional information related to stakeholders (e.g., for worker stakeholders: fair salary, working environment, health and safety etc.) collected for SLCA other than ELCA and LCC, however, provides useful information for enhanced sustainability. Thirty one sub-indicators under five types of stakeholders (workers, local community, society, consumers and value chain actors) and six impact categories (Human rights, working condition, health and safety, cultural heritage, governance, socio economic repercussion) are suggested by the UNEP. As suggested by the UNEP-SETAC, these indicators can be reshaped, refined and varied according to the requirements of a particular region for socio-economic and cultural differences. A similar framework of SLCA was published by the European Commission of Joint Research Centre in 2016. It recommends the use of Sustainable Development Goal (SDG) initiatives for social indicators. Out of 17 SDG indicators in which 8 are directly linked with the social perspectives ([Sala et al., 2015b](#)).

Since the concept of SLCA is relatively newer than ELCA and LCC, there are quite limited research has been conducted on the SLCA (only 4% among the reviewed articles) of alternative fuels in the literature. However, few interesting studies have been carried out in this area as [Manik et al. \(2013\)](#) has converted the qualitative values of social parameters for quantitative analysis for the social sustainability assessment for palm biodiesel production in Jambi province, Indonesia. Twenty-four indicators were developed by the authors based on the UNEP-SETAC guidelines and literature reviews. Social sustainability gaps were calculated based on different stakeholder's perception and expectation on indicators. Finally, these gaps were multiplied with the weight of each criteria to obtain the final scores for social sustainability performance and lower gap would thus offer better sustainability. It has been found that alternative fuel can augment regional development by creating new jobs and by improving the income level but comprehensive social issues over the life cycle of a fuel are needed to be assessed ([Macombe et al., 2013](#)). In the previous case studied by [Manik et al.](#) for example, revealed that palm biodiesel production in Jambi province in Indonesia was socially sustainable from the human rights, governance and socio-economic repercussion perspectives but from working condition (gap: - 1.60; due to mainly terribly low salary) and cultural heritage (gap: - 4.25) perspectives due to conversion of the massive rain forest to palm plantation field resulting displacement of several indigenous and ethnic people which required government attention. [Ekener-Petersen et al. \(2014\)](#) also conducted a social screening of few traditional and alternative fuels based on social hotspot database (SHDB) indicators developed by the New Earth, USA. SHDB mainly consists of 22 social themes under five social categories and each theme has certain number of indicators. All indicators are ranked according to their risk level (i.e. very high risk, high risk, medium risk and low risk) for a certain sector of a particular country. Indicators and qualitative data used for the database were mostly based on World Bank and International Labour Organization (ILO). Major limitation for this database is that it can only be applicable to macro-level study utilizing national database and therefore, there is a need for the development of a region as well as product specific databases. Hybridized method by combining process base LCA and Social LCA to assess the ethanol bio-refineries in Brazil has also been documented by the [Souza et al. \(2018\)](#). Though this holistic approach assisted to conduct comprehensive social sustainability but study considered only workers as stakeholders. Other than transportation fuels, SLCA has also been performed in different sectors using different level of scales (e.g., 1 to 7, 1 to 5, - 2 to + 2 etc.) for data collection followed by MCDA techniques. The selection of impact categories and indicators were the most challenging part for SLCA due to the region specific condition. As of now social LCA are still suffering from lack of actual tools, data and assessment methods ([Petti et al., 2018](#)).

Since SLCA's indicators are based on the local stakeholders' interest, local knowledge and impact categories and expert opinion, the impacts of SLCA vary with regions. There is also a challenge associated with data collection to develop proper indicators for a specific region before conducting SLCA. Size, growth and structure of population, literacy rate, poverty level, natural resources, expenditure on fuel and food, habit of communication and transportation all these factors have influence on social perception and indicators. Indicators, in this regard, should be chosen based on region specific conditions and then refinement of indicators can

be done based on expert opinions. Whilst indicators were selected based on the different internationally agreed guidelines and literature reviews, these indicators do not represent all life cycle stages of a fuel i.e. all stakeholders were not considered in the analysis (Wang *et al.*, 2017). In addition, in the previous studies, the scenario analysis involving different possible cases in the context of a particular region with SLCA were missing which was quite important to allow improved decision formulation based on the different outcomes. Due to these associated challenges, it is still difficult to conduct SLCA properly. However, it is being considered as an indispensable component of TBL sustainability assessment when using a holistic life cycle assessment approach.

Life Cycle Sustainability Assessment (LCSA)

In order to evaluate TBL sustainability, a product should be evaluated from social, economic and environmental objectives. LCA concept can be applied to develop a holistic sustainability assessment toolbox provided newly emerged SLCA tool can be combined with ELCA and LCC tools. LCSA can actually offer a guideline for sustainable consumption and production of goods and services. UNEP-SETAC guideline discussed the concept of LCSA in 2011 which was the evaluation of positive and negative environmental, economic and social impacts of a product/service throughout its life cycle. Different purposes of ELCA, LCC and SLCA have to be described conspicuously under the goal and scope of LCSA (UNEP, 2011). There has to be identical system boundaries for all three components of LCSA and reason of excluding or including any stages have to be justified based on the goal and scope. Impacts for ELCA and LCC could be ascertained on the basis of functional unit like per unit basis but for SLCA no comparable impact assessment steps are required due to the qualitative nature of data. The UNEP-SETAC report also suggested to conduct more researches on LCSA in the different parts of the world to make the LCSA as operational and trusted decision making tools.

Except, UNEP-SETAC guideline, Kloepffer (2008) also provided two concepts of life cycle sustainable assessments. First one was to conduct ELCA, LCC and SLCA separately with identical system boundaries and then to combine together as shown in Eq. 1. The other one was to conduct new LCA which would have one LCI model for all three components (Eq. 2).

$$LCSA = ELCA + LCC + SLCA \quad (1)$$

$$LCSA = 'LCA \text{ new}' \text{ (Including LCC and SLCA as additional impact categories in Life Cycle Impact Assessment)} \quad (2)$$

The author believed that in future ISO 14040 and ISO 14044 could be revised to accommodate option 2. They also expressed that problem with the data availability, selection of indicators was the main challenge of SLCA which needed to overcome. However, it was advised that sustainability had to be established in national, regional, global and even in community level and because of that there were no alternative to investigate further. Similarly, Guinee *et al.* (2010) believed that LCSA would be the future of LCA which would cover the people, planet and prosperity. Like Walter Kloepffer, they have also discussed a conceptual framework by combining process based ELCA with SLCA and LCC for the same system boundary. Three levels of study according to the objectives namely economy wide (i.e. country/region), Meso level (i.e. community or organization) and product (i.e. fuel in this case) level were mentioned in the frameworks. In this regard, Sala *et al.* (2013) suggested that LCSA should be developed with better sustainability which also should include the approach of integrating analytical and descriptive approaches. Zamagni *et al.* (2013) had also expressed that feasibility and testing of LCSA has been accomplished but there should be more practical frameworks with the real case studies in different territories across the world to make the LCSA operational.

There are fairly limited research on LCA which takes into account all three pillars of sustainability of vehicle fuels as economic and social pillars are usually ignored or inadequately conducted. Osorio-Tejada *et al.* (2017) for instance, employed Analytical Hierarchical Process (AHP) method of MCDA technique based on various indicators from three perspective of sustainability to evaluate the biodiesel and LNG as a transport fuel in Spain. Though the comprehensive study was conducted by the authors but selected only three indicators from each pillars of sustainability (Environment: GHG emissions, NO_x and PM, Noise; Economic: Initial and maintenance costs, Reliability, Legislation; Social: Employment, Social benefits, Social acceptability) which were not enough and were also not from different life cycle stages of fuel. For example, important environmental indicators like eutrophication, acidification, ODP and Photo chemical Oxidation potential (POCP) which were found to increase with alternative fuels in many cases were not included in the study. Similarly, aggregated life cycle cost which is termed as LCC is not included as economic indicators as well. Even for social analysis, fuel production stages were not included in the analysis and most importantly authors did not choose the sustainability indicators based on the regional perspective rather depended on global indicators based on a review article published by (Wang *et al.*, 2009). Another study by Onat *et al.* (2016) in USA, evaluated traditional conventional IC engine, hybrid, plug-in hybrid, and battery electric vehicles by considering dynamic modeling. To build the relationship among the indicators, authors used a loop diagram by establishing the relations among the indicators. Though authors introduced a new approach but like previous study as mentioned above, only seven indicators (GHG emission, PM, POCP, Vehicle ownership cost, Contribution to GDP, Employment generation and Human health) were chosen for the TBL assessments. Moreover, the authors agreed that this model and analysis were only in USA but they may not be applicable to other economy. To conduct an LCSA, EIOLCA model and combination of EIOLCA model with process based LCA were also employed (Onat *et al.*, 2014) but as mentioned earlier EIOLCA is not particularly suitable for product level as its calculation are based on the transactions of a particular economy.

Table 2 Summary of LCSA literature

<i>Reference</i>	<i>Sector/product</i>	<i>Basis of indicator selection</i>	<i>Integration method of TBL indicators</i>	<i>Decision context of sustainability</i>
Akber <i>et al.</i> (2017)	Electricity generation	Environmental indicators: CML impact assessment method; LCC and SLCA indicators: literature survey	MAVT, MCDA technique; equal weights for all sustainability indicators	0–1 scale; the higher the score, the better the sustainability
Li <i>et al.</i> (2017b)	Photovoltaic application	Review based article and stakeholders opinion	No integrated single score result	0–100 scale; the lower the score, the better the sustainability
Osorio-Tejada <i>et al.</i> (2017)	Alternative fuel	Review based article	AHP, MCDA technique; Weighting based on the related stakeholders interest	0–1 scale; the higher the score, the better the sustainability
Onat <i>et al.</i> (2016)	Alternative fuel vehicle	Review based article	No integrated single score result; established mutual cause-and-effect relationships between indicators	All indicators are compared with base case scenario
Atilgan and Azapagic (2016)	Electricity generation	Environmental indicators: CML impact assessment method; LCC and SLCA indicators: literature survey	MAVT, MCDA technique; equal weights for all sustainability indicators; scenario analysis by using different weighting	The higher the score, the better the sustainability
Onat <i>et al.</i> (2014)	Alternative fuel vehicle	EIOLCA method	7 indicators are presented in a radar chart to compare alternative fuels	0–1 scale; the lower the score, the better the sustainability
Martínez-Blanco <i>et al.</i> (2014)	Fertilizer production	Environmental indicators: based on previously published environmental indicators; LCC indicators: aggregated life cycle cost; Social indicators: SHDB database	No integrated single score result. Indicators are discussed separately based on the functional unit	ELCA and LCC conducted for per ton of fertilized tomato; SLCA included risk categories (i.e. low, medium, high and very high)
Li <i>et al.</i> (2017a)	Grid connected photovoltaic	Environmental indicators: CML2001; LCC and SLCA indicators: Literature survey and stakeholders opinion	Equal weights for all indicators; a likert scale (1–3) was provided for indicator assessment, where 1 stands for the best performance	All scores are added to obtain a single sustainability score; where lower score mean better sustainability
Keller <i>et al.</i> (2015)	Biorefinery	Based on previous literature	No integrated single score result	Indicators are divided into advantageous (+), neutral (0), disadvantageous (–) categories after setting up a benchmark
Luu and Halog (2016)	Rice husk based bioelectricity	By using PROSUITE (prospective sustainability assessment of technologies) framework	Weighting was accomplished based on the PROSUITE model; only 5 endpoint impacts are weighted for single score result	weighted sum results and overall ranking are presented based on the impact assessment results

Table 3 Benefits and challenges of LCSA

Benefits	Challenges
- Using LCSA, the complex information of environmental, economic and social information are presented in a simplified and structured form (Keller <i>et al.</i>, 2015; Luu and Halog, 2016; Sala <i>et al.</i>, 2013) - LCSA can help achieve balance between sustainability pillars by providing comprehensive picture throughout the product life cycle (Keller <i>et al.</i>, 2015) - LCSA supports organization to implement their strategy effectively by knowing their products/services impacts (UNEP, 2011) - Especially, product development strategies can be designed by knowing weaknesses of three pillars of sustainability throughout the product life cycle (Gencturk <i>et al.</i>, 2016). - LCSA supports decision makers/policy makers to make a decision for selection of sustainable technologies (Buchert <i>et al.</i>, 2015) - Consumers can select/identify environmentally friendly, socially responsible and cost efficient product through the LCSA initiative (UNEP, 2011) - Sustainable production, consumption and new labelling initiative can be implemented by using the LCSA results (UNEP, 2011)	- Lack of data and method especially for SLCA (Akber <i>et al.</i>, 2017; Keller <i>et al.</i>, 2015) - Unavailability of sufficient number of practical case studies (Martínez-Blanco <i>et al.</i>, 2014) and limitation of understanding of three pillars of sustainability (Zamagni <i>et al.</i>, 2013) - There are no established consensus in the weighting steps among the different sustainability indicators (Akber <i>et al.</i>, 2017) - Current LCSA frameworks can not accommodate proper scenario and sensitivity analysis properly from the aspect of TBL sustainability required for life cycle based study (Guinée, 2016) - There is a challenge to adopt SLCA indicators for a particular region as there is no appropriate consensus (Martínez-Blanco <i>et al.</i>, 2014; Petti <i>et al.</i>, 2018) - Limitation of method for integration of TBL sustainability indicators (Nguyen <i>et al.</i>, 2017; Sala <i>et al.</i>, 2013) - Perspective of different stakeholders throughout the life cycle of a product are yet not fully covered by the current LCC and SLCA studies under LCSA (Zamagni <i>et al.</i>, 2013)

There are some effort being made to conduct sustainability by considering all the three aspects of sustainability for other sectors as well as for the energy sector (Akber *et al.*, 2017), fertilizer production (Martínez-Blanco *et al.*, 2014), bio-refinery (Keller *et al.*, 2015), heat pump (Huang and Mauerhofer, 2016) and solar photovoltaic application (Li *et al.*, 2017a). Some recent case studies of LCSA with indicator selection procedure, method of TBL indicators integration and sustainability assessment procedure are presented in Table 2. Most of these studies relied on MCDA techniques by choosing relevant indicators for three pillars or objectives of sustainability and a scoring method that used a Likert scale was used in most of these LCSA studies. Though the authors in some of these cases conducted a comprehensive study but life cycle approaches and guidelines such as different stages of LCA, FU, system boundaries were not explicitly discussed and used in most of this studies. Besides, as discussed for Osorio-Tejada *et al.* study, there is a similar limitation regarding sustainability indicators. Akber *et al.* for example, conducted a detail LCSA pertaining to Pakistan electricity sector and followed the life cycle guidelines and approaches but only 4 socio-political indicators (direct employment, total employment, imported fossil fuel avoided and diversity of fuel mix) were selected for their study which did not include the association of stakeholders such as consumers, workers, local community and value chain actors. As the weighting of indicators are based on expert opinion, MCDA techniques can yield different results for different studies.

The benefits and challenges of LCSA conducted to date are summarized in the Table 3. Sensitivity analysis and robustness are the two key significant techniques of LCA that are needed to be incorporated into LCSA to conduct a real life cycle assessment involving interconnections and interdependencies between three pillars of sustainability (Clímaco and Valle, 2016). As discussed earlier, most of the previous LCSA studies did not consider the whole life cycle of a product (especially all stakeholders were not covered during SLCA as mentioned in the SLCA section and as mentioned in the ELCA section only 25% ELCA studies considered both fuel and vehicle life cycle) which was required to have the actual outcomes of TBL assessments. Besides, limited numbers of indicators were chosen for country or economy level assessment which did not actually reflect the region specific conditions as every region has its unique socio-economic political and climatic conditions. Current LCSA frameworks are not robust enough to analyse the actual results of LCA, LCC and SLCA simultaneously and could not demonstrate the interdependencies between three pillars of sustainability. Moreover, there exists several challenges of SLCA like uncertainties of results and data quality which entirely depends on human perspectives and experts' opinion. Therefore, holistic LCSA frameworks with practical case studies are required around the world for comprehensive TBL sustainability assessment.

Lessons Learned and Future Research Directions

It is evident in the above mentioned studies that there is a research gap within life cycle assessment from the perspective of TBL sustainability assessment of alternative transport fuel. More holistic frameworks and practical case studies should be required to conduct the LCSA, which will reflect all three aspects of sustainability as well as follow the guidelines of LCA adequately. Both fuel cycle and vehicle cycles or any associated change in the vehicles due to use of alternative fuels need to be considered within the system boundary to examine the whole life cycle impacts. Best practice LCA guide line for a particular country or region should be adopted to alleviate the dissimilarities of assessment procedures among the LCA practitioner. It was observed that authors quite often selected sustainability indicators from previous literatures and internationally agreed guidelines which literally did not reflect the actual scenario of particular regions. Due to these reasons, selection of triple bottom line indicators and impact assessment should be in line with the best practice guideline of a particular country/region and should reflect the scenarios of the region.

Possible scenario analysis will also be required to cover the future cases. Required number of impact categories and indicators should be devised based on a region/country as it changes with location and places. As of now, mostly MCDA techniques were used to integrate triple bottom line impacts of ELCA, LCC and SLCA. More novel methods and techniques are needed to assess sustainability hotspots of fuels which are capable of handling both qualitative and quantitative outcomes. Moreover, it is necessary to develop threshold values for sustainability assessments for each alternative fuels for a particular region for sustainability assessment (Sala *et al.*, 2015a). The threshold values for environmental, economic or social score of a particular fuel in fact represent the best or sustainable practice (Lim and Biswas, 2017). Based on the review, it is also found that there is a need to conduct LCA regionally to obtain a better sustainability outcome as LCA result of one region cannot be used in another region due to the data variability. Therefore, more region wise LCA should be conducted for informed decision making processes.

Conclusion

The study has provided a comprehensive review of the existing research in the field of environmental, social and economic analysis and life cycle assessment of alternative fuels for road vehicles. On the basis of the lesson learnt through LCA, LCC and SLCA, the gaps have been identified for future research. There is a need for a holistic framework for life cycle sustainability assessments to evaluate a transportation fuel from triple bottom line objectives. To make the LCSA results more acceptable, assessment should be conducted with the local data mainly because of local policies, socio-economic factors and region specific geographical and climatic variations. This is also because of the differences in regions/countries' underlying assumptions, considerations and life cycle assessment methods. It is suggested from the review that there should be region or country wise databases and best practice guidelines for LCA, which can alleviate many issues and dissimilarities for the LCA practitioners. The findings of the review of the literature on alternative fuels have opened new avenues for future research in this area of life cycle sustainability assessment.

Introduction

Biochar is a porous carbonaceous solid material with a high degree of aromatization and strong antidecomposition ability that is produced by the thermal decomposition of biomass from plant or animal waste under oxygen free or limited oxygen conditions (Pandey *et al.*, 2015). It has received much attention during the last few years for its potential applications in various agronomic and industrial sectors. Biochars have a tremendous range of physical and chemical properties (Gul *et al.*, 2015), which greatly affect their wide applications. Recent evidences suggest that the feedstock and the method by which the biochar is produced has a significant impact on biochar characteristics, including concentrations of elemental constituents, density, porosity, and pH, which collectively impact the suitability of the biochar for various applications. In agriculture, it is used to upgrade the soil quality (Aller *et al.*, 2017; Werner *et al.*, 2018). It slows down the rate of decomposition of nutrients from the soil and hence, enhances the soil quality. In different industries, it is used in waste treatment (Ahmad *et al.*, 2014; Oliveira *et al.*, 2017; Uchimiya *et al.*, 2013) to remove organic contaminants, heavy metals and different kinds of dyes and pigments from textile industries. In power generation, biochar can be used as a fuel because biochar contains a high carbon percentage in it. Biomass has been found to be a very potential source of renewable energy (Tripathi *et al.*, 2016) materials and chemicals.

The main sources of biomass, as a raw material, include agricultural residues, algal biomass, forest residues, manures, activated sludge, energy crops, digestate etc. Biomass may be converted into high-value products using a number of physical, thermochemical and biochemical processes. Biochar is produced by thermochemical conversions, such as pyrolysis, gasification, torrefaction, and hydrothermal carbonization of carbonaceous biomass at high temperature (300–900°C) and under O₂-limiting conditions (Lehmann *et al.*, 2011). The physical, chemical and mechanical properties of biochars depend on the feedstock type and pyrolysis operating conditions (Jafri *et al.*, 2018). The selection of a specific type of feedstock is to a great extent determined by the availability of this material in the region where the biochar is likely to be produced, as this reduces the cost of transport while decreasing the carbon footprint of the biochar technology. Production of the biochar from the biomass does not only depend upon the technique which is employed to produce but it is also a function of the process parameters involved in the production also. Studies on the biomass pyrolysis in the recent past have revealed that the production of the biochar depends upon several factors such as type of biomass, moisture content, and particle size, reaction conditions (reaction temperature, reaction time, heating rate) and surrounding environment (carrier gas type, flow rate of carrier gas) and other factors (catalyst, reactor type).

The main objective of this article is to show the potential of waste biomass for production of biochar which is a valuable material with tremendous applications. This article exhaustively describes the possible raw materials for biochar production, biochar production processes, the properties of biochar, followed by biochar applications and final conclusion is presented.

Raw Materials for Biochar Production

Biochar is produced from a wide range of raw materials, and it has a porous structure and negative surface functional groups. Biomass with varying contents of hemicellulose, cellulose, and lignin may yield biochars with distinctive physicochemical properties. The main sources of raw material for biochar production include: biomass, municipal waste, field residues, and animal waste. These raw materials can be lignocellulosic and non-lignocellulosic biomasses. Lignocellulosic biomass (Mary *et al.*, 2016) are abundant bioresource of plant and animal parts including agro-industrial residues, forest-industrial residues, energy crops, municipal solid waste, and others. The widespread non-lignocellulosic biomass wastes include sewage sludge, manure, algae, animal hair, and bone, etc. are with severe challenges for value-added disposal and utilization, because of their complex and various components. Li and Jiang have presented a review on non-lignocellulosic biomass characteristics, thermochemical behaviors of main components (e.g., C, O, N, P, and metals), characterization methods, conversion process, and the main applications of non-lignocellulosic biochar (Li and Jiang, 2017). Compared with lignocellulosic biomass, the non-lignocellulosic biomass has a greater threat for the ecological environment because of its higher contents of heavy metals and heteroatom like nitrogen, phosphorus, sulfur (Agrafioti *et al.*, 2013). The heavy metals in non-lignocellulosic biomass can be dissolved in a water system, leading to water pollution and accumulation in the food chains (Wang *et al.*, 2016). Cellulose, hemicellulose and lignin compositions of such biomass feedstock are depicted in Table 1.

Biochar Production Processes

Biomass can be converted to renewable fuels through biochemical and thermochemical conversion processes. The important biochemical conversion processes include anaerobic/aerobic digestion, fermentation, and enzymatic or acid hydrolysis. In

Table 1 Lignocellulosic composition (wt%) of certain biomass resources

	<i>DPR</i>	<i>DPL</i>	<i>EFB</i>	<i>DPG</i>	<i>PP</i>	<i>CL</i>	<i>OP</i>	<i>HW</i>	<i>SW</i>	<i>LG</i>
Cellulose	40.40	34.87	38.44	22.22	45	40	54.1	45–50	35–40	38
Hemicellulose	33.08	19.84	24.65	20.44	41	50	49	20–25	20–25	26–29
Lignin	12.49	14.03	25.08	16.01	3	8	12	20–25	27–30	15–19

biochemical conversion, biomass molecules are broken down into smaller molecules by bacteria or enzymes. This process is much slower than the thermochemical conversion process but does not require much external energy. In the anaerobic digestion, bacteria take oxygen from the biomass itself instead of atmospheric oxygen. The products of anaerobic digestion are biogas (a mixture of methane, carbon dioxide) and solid digestate. Only 5%–10% of the feed into the digester is digested by the anaerobic bacteria. The digestate consists of remaining indigestible material. Aerobic digestion, commonly known as composting, takes place in the presence of oxygen. It uses different types of microorganisms that access oxygen from the air, producing carbon dioxide, heat and solid residue (compost). In fermentation, starch is converted into sugars using acids or enzymes. Then sugar is converted into ethanol or other chemicals with the help of yeast. The fermentation of lignocellulosic feedstock requires additional pretreatment (hydrolysis) to breakdown the cellulose and hemicellulose into simple sugars. Hydrolysis can be achieved by the use of acids, enzymes or hydrothermally (Basu, 2013). The lignin is not converted and is left for thermochemical conversion. Biochar is not a product of biochemical conversion, as a result, biochemical conversion methods are of no importance in the production of biochar. Major thermochemical technologies for biochar production include slow and fast pyrolysis, gasification, torrefaction, and hydrothermal carbonization. Biochar yield greatly depends on the adaption of pyrolysis type. Slow pyrolysis performed at longer residence time and at a moderate temperature (350–550°C) in absence of O₂ results in higher yield of biochar (30%) than the fast pyrolysis (12%) or gasification (10%).

Thermochemical Conversion Processes

There are many types of thermochemical conversion processes through which biomass is converted to solid, liquid and gaseous products. Thermochemical conversion processes use high temperature to breakdown the bonds of organic matter, including combustion, gasification, and pyrolysis (Lehmann and Joseph, 2009). Combustion is simply a burning of biomass in air. Chemically it is high temperature exothermic oxidation of biomass in the presence of oxygen to form carbon dioxide (CO₂) and water vapor (H₂O), hot flue gas. Char (contains some organic carbon) and ash (typically includes inorganic oxides and carbonates) are the solid byproducts of combustion. Combustion temperatures are usually in the range of 700–1400°C. Combustion is not a preferred method of biochar production as it converts most of the carbon in the biomass into CO₂. Gasification is performed at temperatures greater than 800°C under reduced oxygen atmosphere to avoid complete combustion (Basu, 2013). Gasifiers are designed to produce gaseous products of incomplete combustion comprising carbon monoxide (CO), hydrogen (H₂) together with CO₂, nitrogen (N₂) and moisture (H₂O). Gasification is also a poor choice for biochar production as it converts most of the carbon in the biomass into CO and CO₂.

Pyrolysis Process

Pyrolysis is a thermal decomposition process that takes place in the absence of oxygen to convert biomass into three distinct product fractions: solid residue (biochar), condensable vapors resulting liquid product fraction (bio-oil) and non-condensable gaseous products. Once oxygen is removed, combustion cannot occur instead pyrolysis happens. Pyrolysis temperatures are usually between 300 and 700°C. Pyrolysis is the most promising technique to convert biomass into biochar and bio-oil. Lower pyrolysis temperatures and longer residence times tend to produce more biochar. High temperatures and longer residence times increase the production of gas. Moderate temperatures and short residence times tend to produce more liquids (Bridgwater, 2012).

There are different pyrolysis processes including torrefaction, slow (conventional) pyrolysis, intermediate pyrolysis, fast pyrolysis, flash pyrolysis, microwave pyrolysis, and hydrothermal carbonization. Various operating conditions are used in these processes, for example, residence time can vary from less than 1 second to hours, heating rate can vary from less than 1°C/s to more than 1000°C/s and temperature can vary in the range from 300 to 700°C or higher. As each type of pyrolysis produces different proportions of the three types of products (biochar, bio-oil, and gas), careful selection of the pyrolysis process is important to obtain the final desired product. The primary conversion of biomass during the pyrolysis process can be described by three pathways; char formation, depolymerization, and fragmentation (Collard and Blin, 2014). Char formation is generally favored by intra- and intermolecular rearrangement reactions resulting higher thermal stability of the residue. This pathway is characterized by the formation of benzene rings and the combination of these rings into an aromatic polycyclic structure. These rearrangement reactions are generally accompanied by the release of water or non-condensable gas (devolatilization). Depolymerization is characterized by breaking of polymer bonds, followed by stabilization reactions to produce monomer, dimer and trimer units. These volatile molecules are condensable at ambient conditions and found in liquid fraction. Fragmentation consists

Fig. 1 Conceptual pyrolysis process.

Table 2 Operating conditions of various pyrolysis processes and their product fractions (bio-oil, biochar, and gas)

Mode	Condition	Liquid (bio-oil)	Solid (biochar)	Gas (syngas)	Heating rate
Fast pyrolysis	Moderate temperature (425–600°C), Short vapor residence time (< 2 s)	75% (25% water)	12%	13%	10–1000°C/s
Intermediate pyrolysis	Low to moderate temperature (450–550°C), Moderate hot vapor residence time (10–20 s)	50% (50% water)	25%	25%	1–10°C/s
Slow pyrolysis	Low to moderate temperature (300–550°C), Long residence time (hours to days)	30% (70% water)	35%	35%	1–0.8°C/s
Gasification	High temperature (> 800°C) Long vapor residence time	5% tar (55 water)	10%	85%	
Torrefaction	(450–550°C), (< 2 h)	20%	75%	5%	< 1°C/s
Hydrothermal Carbonization	(< 200°C), (1–16 h)				< 1°C/s
Flash Pyrolysis	(750–1000°C), (0.5 s)				> 1000°C/s
Microwave-Assisted Pyrolysis	(400–800°C),				

the breaking of polymer bonds and even monomer bonds result in the formation of non-condensable gasses and a range of organic vapors which are condensable at ambient conditions (Collard and Blin, 2014).

The gas and vapor products of primary conversion are unstable under pyrolysis temperatures and, with sufficient residence time, can undergo secondary reactions such as cracking or recombination reactions. Cracking reactions consist the breaking of volatile compounds into lower MW (molecular weight) molecules. Recombination consists the combination of volatile compounds into higher MW molecules, which may not be volatile under pyrolysis temperatures. Recombination reactions also result in the formation of secondary char. Primary char can act as a catalyst to the secondary reactions (Collard and Blin, 2014).

As a result of high heating rates and short residence times, fast pyrolysis tends to yield higher proportions of oils. In contrast, slow pyrolysis tends to yield higher proportions of biochars because of slow heating rates and longer residence times. The occurrence of primary and secondary reactions in thermal decomposition of biomass highlight the fundamental difference between fast pyrolysis and slow pyrolysis.

Pyrolysis requires relatively dry feedstock (usually moisture content <30 wt%, but moisture contents of ~10 wt% are preferred), and grinded to different particle sizes based on the type of pyrolysis. A general scheme of a pyrolysis process is represented in Fig. 1.

Feedstock with high moisture contents consumes more energy to account for increasing heat of vaporization during the heating of biomass towards the pyrolysis temperature. Additionally, the gases and vapors produced in pyrolysis using a high moisture feedstock are diluted with steam and have a lower calorific value. Wet biomass, typically with 70 wt% or more water can be converted using hydrothermal carbonization processes. The common processes include slow and fast pyrolysis, and the most successful approach for high-yield biochar production is via slow pyrolysis as directed in Table 2.

Torrefaction process

Torrefaction, a mild form of pyrolysis, involves heating the feedstock to temperatures of 200–300°C at slow heating rates (less than 1°C/s) in the absence of air under atmospheric pressure conditions. Torrefaction removes water as well as superfluous volatiles and partly decomposes the biopolymers (cellulose, hemicelluloses, and lignin) by giving off organic volatiles. It tends to yield higher proportions of solid (torrefied biomass) in addition to liquid and non-condensable gaseous products. As specified by the EBC (2012), the molar oxygen to carbon (O/C) ratio of biochar should be less than 0.4. But torrefied biomass tends to have higher

oxygen to carbon O/C) ratio than the ECB specification of biochar. Therefore, torrefied biomass cannot be referred to biochar. Torrefied biomass has physicochemical properties in-between that of raw biomass and biochar. Torrefaction is a pre-treatment method that is used primarily for moisture removal and densification of biomass, which will reduce the cost of transportation and increase the heating value of biomass. Torrefaction also increases the hydrophobicity, grindability and reduces the biodegradability compared to the untreated biomass feedstock. Torrefied biomass can be stored long-term without degradation. A typical mass yield from torrefaction is 70%–80% and energy yield is 80%–90%.

Slow pyrolysis process

The slow pyrolysis is characterized by moderate temperatures (300–550°C), slow heating rates (0.1–0.8°C/s) and longer residence time (5–30 min or even 25–35 h) (Roy and Dias, 2017). Slow pyrolysis aims at maximizing the yield of biochar by promoting secondary reactions, which is achieved by longer vapor residence times. The biochar produced in slow pyrolysis consists of both primary and secondary char. The slow heating rate with moderate pyrolysis temperatures also promotes the production of biochar. Biochar yield depends on the feedstock properties and pyrolysis conditions such as processing temperature, heating rate and pyrolysis environment (Roy and Dias, 2017). Biomass containing more minerals yields less biochar. The overall slow pyrolysis process can generally be exothermic due to the extensive occurrence of secondary reactions. Slow pyrolysis can accept a wide range of particle sizes (5–50 mm).

Intermediate pyrolysis process

In intermediate pyrolysis, the reaction is faster than slow pyrolysis but slower than fast pyrolysis. It occurs in the temperature range of 450–550°C, at higher heating rate than slow pyrolysis with residence time ranging from 10 to 30 s and produces less biochar than slow pyrolysis process (Bridgwater, 2012; Pandey *et al.*, 2015). Intermediate pyrolysis occurs at controlled heating rates thus inhibiting the formation of high molecular weight tars and yielding products (biochar, bio-oil, and gases) with different product qualities. In intermediate pyrolysis, the biomass particles sizes and shapes are less critical than in fast pyrolysis. It can process a wider variety of biomass, larger particles up to pellets and chips and also material with a water content of up to 40% (Pandey *et al.*, 2015).

Fast pyrolysis process

The fast pyrolysis typically involves high temperatures, high heating rates (10–1000°C/s) and short residence times (0.5–2 s) (Roy and Dias, 2017). Fast pyrolysis prevents secondary reactions from taking place by having short vapor residence times (rapid removal and quenching of the condensable vapors) and by maintaining high biomass heating rates thereby maximizing the yield of condensable vapors (bio-oil). The distribution of products (bio-oil, biochar, and gasses) depends on the biomass composition and rate and duration of heating. If bio-oil is the product of interest, the optimum pyrolysis temperature range is 425–600°C with the peak temperature below 650°C. However, the peak temperature can be up to 1000°C, if the production of gas is of primary interest (Basu, 2013).

A finely ground biomass feed (usually < 1 mm) is required to achieve very high heat transfer rates and thereby very high heating rates which reduce the mass and heat transfer limitations. The biochar yield in fast pyrolysis is generally low as only primary char is being produced. The overall fast pyrolysis process is highly endothermic due to the absence of secondary reactions. Fast pyrolysis prefers biomass with low moisture content (< 10 wt%) in order to minimize the water in the product bio-oil. Low moisture content also facilitates grinding the feed to give sufficiently small particles to ensure rapid heating and fast pyrolysis (Bridgwater, 2012).

Flash pyrolysis process

Flash pyrolysis also aims to maximize the yield of liquid. It is characterized by high temperatures, higher heating rates (> 1000°C/s) and shorter residence times (< 0.5 s). The main product distributions of flash pyrolysis are similar to that of fast pyrolysis. It occurs in the temperature range of 800–1000°C (Pandey *et al.*, 2015). Very fine particles of biomass feed (< 0.2 mm) is usually required.

Hydrothermal carbonization process

Most biomass materials are wet and have moisture contents range up to 95 wt%. Biomass with more than 30 wt% moisture content requires drying prior to pyrolysis. Hydrothermal carbonization (HTC) involves the application of heat and pressure to convert biomass in the presence of water into carbonaceous biofuel. It is a promising technique to convert the wet biomass into biofuels by omitting the energy-intensive drying process. Water plays an active role as a solvent and reactant. When biomass feedstock in water is heated at low temperatures (< 200°C) in a sealed vessel at autogenous pressure, mostly solids (called hydrochar) are formed in a process known as hydrothermal carbonization (HTC). At higher temperatures (between 200 and 350°C), hydrothermal liquefaction (HTL) takes place and the biomass feedstock is mostly converted into a liquid product (bio-oil). Near and above the critical point of water (374°C and 22.1 MPa), hydrothermal gasification (HTG) takes place and the biomass is mostly converted into a mixture of non-condensable gases (H₂, CO, CH₄, and CO₂). Hydrochar has higher H/C ratios than biochar specifications.

Microwave assisted pyrolysis process

In conventional heating, heat is transferred to the material surface (by convection, conduction, and radiation) and subsequently from the surface to the interior of the material by conduction as a result of temperature gradients. On the other hand, microwave

Table 3 Merits and demerits of various pyrolysis processes

Pyrolysis type	Merits	Demerits
Torrefaction	Higher proportions of solid yield (torrefied biomass)	Torrefied biomass have higher O/C ratio than biochar specification
Slow pyrolysis	Maximum yield of biochar. Can accept a wide range of particle sizes	
Intermediate pyrolysis	Can process a wide range of particle sizes and also material with a water content of up to 40 wt%	Produce less biochar than slow pyrolysis
Fast pyrolysis	Higher yield of bio-oil	Biochar yield is generally low. Finely ground biomass feed (usually < 1 mm) is required. Prefer biomass with low moisture content (< 10 wt%)
Flash pyrolysis	Maximum yield of bio-oil	Very fine particles of biomass feed (< 0.2 mm) is usually required
Hydrothermal carbonization	Can convert the wet biomass into biofuels. Drying is not required	Produce solid product (hydrochar) having higher H/C ratio than biochar specification
Microwave-assisted pyrolysis	Uniform heating throughout, rapid heating rate, volumetric and selective heating	Require electricity which is an expensive high quality-energy

energy is delivered directly into materials within an electromagnetic field. The electromagnetic field enters the material and generates thermal energy throughout the penetration depth by dielectric heating through interaction with polarizable dipoles present in the material and heat the material from inside. Microwave heating requires a material with a high dielectric constant. The dielectric constant is a measure of the ability of a material to absorb microwave energy. Biomass has a relatively low dielectric constant. As a result, microwave pyrolysis requires catalyst as well as microwave absorbers to improve the heating. The presence of water in biomass may increase the heating rate of microwave pyrolysis, due to the high dielectric constant of water in comparison with biomass (Yu *et al.*, 2017). Microwave-assisted pyrolysis usually operates in the temperature range at 400–800°C.

Some of the advantages of microwave-assisted pyrolysis over conventional pyrolysis include uniform heating throughout, rapid heating rate, volumetric and selective heating. Microwave heating provides ease of operation by instant on/off control and improves the yield and quality of the products. It reduces the formation of hazardous product and minimizes pollutants emission, making the technique environmentally friendly (Yu *et al.*, 2017). The other advantages include high heating efficiency as heating is in situ, ability to handle wet biomass without drying and ability to pyrolyse large biomass particles. The disadvantage of microwave assisted pyrolysis is that it requires electricity which is an expensive high-quality energy compared to the heat generated by the combustion of pyrolysis gases and vapors in conventional pyrolysis.

The merits demerits of the pyrolysis processes are summarized in the following table (Table 3).

Biochar Quality

The European Biochar Certificate (EBC, 2012) define biochar as a “heterogeneous substance rich in aromatic carbon and minerals. It is produced by pyrolysis of sustainably-obtained biomass under controlled conditions with clean technology and is used for any purpose that does not involve its rapid mineralization to carbon dioxide and may eventually become a soil amendment”. This definition differentiates biochar from other forms of carbonaceous materials such as char, charcoal. The sources of biomass for the production of biochar need to be renewable and sustainable. The intended end use of biochar is soil management and C (carbon) sequestration.

The major component of plant biomass is cellular lignocellulosic material, which is the non-starch fibrous part of the plant materials. The three major constituents of lignocellulosic biomass are cellulose, hemicellulose, and lignin (Basu, 2013). The main constituent of plant cell wall is cellulose, which provides structural support. The second and third most abundant polymers in lignocellulosic biomass are hemicellulose and lignin, respectively. These three forms of polymers are responsible for most of the physical and chemical property modification during the pyrolysis process. The mechanisms of pyrolysis of these polymers are chemically different from biomass species to species. Cellulose and hemicellulose decompose over a narrower temperature range whereas lignin degrades over a wider temperature range compared to cellulose and hemicellulose. Some other compounds present in biomass include inorganic compounds and organic extractives. The inorganic compounds constitute less than 10% by weight of biomass, forms ash in the pyrolysis process. Organic extractives of biomass refer to the nonstructural components that can be extracted by polar or nonpolar solvents. These include fats, waxes, proteins, terpenes, simple sugars, gums, resins, starches, alkaloids, phenolics, pectins, glycosides, mucilages, saponins, and essential oils. Also, biomass has a substantial quantity of free and bound water.

The biochar properties will depend on the feedstock material characteristics and pyrolysis conditions used for the production of biochar. The main parameter that determines the degree of devolatilisation of the biomass is the pyrolysis temperature. Water, both free and bound, is the first constituent removed in heating of biomass to temperatures up to 160°C. Thermal decomposition of biomass begins with devolatilisation/decomposition of extractives at temperatures < 220°C. Hemicellulose is the least stable polymer and break down first at temperatures of 220–315°C. Cellulose has a high degree of polymerization and exhibits

higher thermal stability. It decomposes in the temperature range 315–400°C. Lignin is the most difficult component to pyrolyse which decompose in a wide temperature range from 160 to 900°C (Yang *et al.*, 2007).

Commonly measured quality parameters of biochar include carbon content, bulk density, carbon stability, volatile compound content, surface area, nutrient content, heavy metals, pH value, water and ash content, PAH, water holding capacity, porosity, elemental composition (carbon, hydrogen nitrogen and oxygen), cation exchange capacity and electrical conductivity (EBC, 2012; Song and Guo, 2012). The quality of biochar varies with the feedstock type and pyrolysis process. Pyrolysis parameters such as heating rate, residence time and final temperature greatly influence the biochar quality. Pyrolysis temperature plays an important role in biochar properties such as elemental composition, particle size, specific surface area, pore size distribution, thermal capacity, and electrical conductivity.

Depending on the application of biochar, some quality parameters are more important than others. In crop production, the important quality parameters of biochar include pH, volatile compound content, ash content, water holding capacity, bulk density, pore volume and specific surface area (Song and Guo, 2012). Carbon stability is a critical quality parameter in carbon sequestration and soil fertility enhancement. The other important quality parameters in soil fertility enhancement include surface area and nutrient content. One of the most important characterization parameters of biochar is the molar hydrogen to carbon (H/C) ratio, it is an indicator of the degree of carbonization and the stability of biochar. The value of H/C ratios greater than 0.7 indicate a low biochar quality and pyrolysis deficiencies. Molar oxygen to carbon (O/C) ratio is also relevant for characterizing biochar and differentiating it from other carbonization products (EBC, 2012). The value of O/C ratio greater than 0.4 indicates a lower biochar stability.

The molar H/C and O/C ratios of lignocellulosic biomass are approximately 1.5 and 0.7, respectively. During pyrolysis, the biomass undergoes devolatilization and the solid portion gets enriched in carbon. The H and O are preferably removed over C and the H/C and O/C ratios tend to decrease as biomass undergo its transformation into biochar. The H/C and O/C ratios are used to assess the degree of aromaticity and maturation (Lehmann and Joseph, 2009).

Properties of Biochar

Characterization of biochar for proximate and ultimate analysis reveals the different biochar properties. Important physico-chemical properties include porosity, surface area and pH which all have an effect on its application to soil. Biochar is made up of elements such as carbon, hydrogen, sulfur, oxygen, nitrogen as well as minerals in the ash fraction. The properties of biochar will thus vary depending upon the production conditions and the nature of the feedstock used. For example, during the thermal oxidation of biomass to produce biochar, the inherent carbon is lost in the forms of CO₂, CO, CH₄, and various hydrocarbons. Also, there are cracking and devolatilization creating bigger pore holes inside the biochar if produced at higher temperatures. Elemental compositions of biochars from different biomass resources are shown in Table 4.

Thus, a biochar with desirable properties can be deduced from both its proximate and ultimate analysis. The lower the O/C and H/C ratios, the higher is the loss of oxygen and hydrogen during the combustion process (Nsamba *et al.*, 2015) producing a product richer in higher elemental carbon. The International Biochar Initiative (IBI) recommends a maximum value of 0.7 for the molar H/C ratio (Mary *et al.*, 2016; Nsamba *et al.*, 2015) to distinguish biochar from biomass that has not been or only somewhat thermochemically altered. Thus suitable working conditions and technologies must be selected in order to produce a biochar of high quality. The pH of biochar from different biomass is around 10 and the microscopic surface structure of biochars ranges from around 3 m²/g for rice husk biochar to around 500 m²/g for biochar from wood (Kan *et al.*, 2016).

Biochar Applications

Biochar is widely used for generation of heat and power, and an addition to soils, in which it serves as a fertilizer and carbon sequestration agent, it also used as an adsorbent for many pollutants from different processing sectors. The application of biochar has been shown to improve soil physical properties, especially in soils with bad soil structure or high bulk density. Biochar is also used as a catalyst (Lee *et al.*, 2017) and support of a catalyst. It can also be used as a filter medium and adsorbent for waste treatment to different industrial effluents.

Table 4 Elemental analysis of biochar produced from some typical biomass

	SC	Euc	SWS	DPR	DPL	EFP	DPG	PP	CL	OP
Ash (%)	9.86	3.60	58.53	5.50	11.58	4.20	2.40

Environmental Applications of Biochar

Biochar, a low-cost carbonaceous material, is emerging as an economical substitute to the activated carbon to remove diverse organic contaminants such as agrochemicals, antibiotics, polycyclic aromatic hydrocarbons, polychlorinated biphenyls, volatile organic compounds and aromatic dyes, and a series of inorganic contaminants (e.g., heavy metals, ammonia, nitrate, phosphate, sulfide etc.) from aqueous, gaseous and/or solid phases.

Biochar has wider environmental applications due to its distinctive characteristics, e.g., high adsorption capacity, high specific surface area, microporosity, and ion exchange capacity. Such variability and predominance of a specific reaction are controlled by specific physicochemical properties of the biochar, which is attributed to feedstock types and pyrolysis conditions used during its production. These two factors greatly change the physicochemical properties such as surface area, polarity, atomic ratio, pH, elemental composition, thus overall surface property of the biochar (Ahmad *et al.*, 2014; Uchimiya *et al.*, 2013). These variations in biochar characteristics have significant implications on its suitability and efficacy in remediation of targeted pollutants.

Applications of biochar in soil not only remediate the pollutants from the soil but also improve the soil properties. Biochar improves physical (e.g., water holding capacity, O₂ content and moisture level), chemical (e.g., pollutants immobilization and carbon sequestration), and biological (e.g., microbial abundance, diversity, and activity) properties of the soils (Gul *et al.*, 2015). These biochar characteristics eventually contribute to soil carbon sequestration, greenhouse gases emission reduction, and therefore contribute to an overall improvement in soil health.

Biochar as Adsorbent

Environmental application of biochar is one of the primary applications of biochar. In addition to being used as soil conditioner and carbon sequestration reagent, biochar has attracted much attention in wastewater treatment field. Recent literatures show biochar as a highly efficient, environmentally friendly, and low-cost adsorbent. Biochar characteristic plays a critical role in contaminant removal, which is often governed by pyrolysis temperature and feedstock type. For example, fully carbonized biochar produced at a higher pyrolysis temperature (> 500°C) has more affinity for organic pollutants due to high surface area, microporosity, hydrophobicity, carbon-to-nitrogen (C/N) ratio, pH, and low dissolved organics. On the other hand, partly carbonized biochar produced at a lower pyrolysis temperature (< 500°C) contains a higher content of dissolved organic carbon and O-bearing functional groups, relatively low porosity and C/N ratio, hence more appropriate for removal of inorganic pollutants. Regarding feedstock types, biochar derived from woody biomass and crop residues has higher surface area compared to that of the solid municipal wastes and animal manure-derived biochars. Other factors such as biochar pH (resulting from pyrolysis condition), biochar residence time, biochar application rate and contaminant type also affect the removal efficiency of biochar. There have been significant research efforts to examine the application of biochar for removal of various industrial organic and inorganic pollutants (Lehmann *et al.*, 2011; Oliveira *et al.*, 2017) depicted in Table 5.

Biochar as Catalyst

Biochar's unique chemical structure with a large surface area and tailored surface functional groups can be easily prepared by activation or functionalization and shows great potential to be used as a versatile catalyst or catalyst support in many chemical processes. Biochar can be easily separated from catalysts by oxidation to recover precious metals. Therefore, the application of biochar as catalyst will not only enhance its utilization but also promote the development of a variety of catalysts. Biochar used in the synthesis of carbon-encapsulated iron nanoparticles, and its catalytic activity on the conversion of synthesis gas to liquid hydrocarbons was evaluated. It was found that the CO conversion was about 95% and the selectivity of liquid hydrocarbon was as high as 68%. Similarly, biochar activated with KOH and sulfonated using fuming H₂SO₄, give a high activity on the transesterification for biodiesel production (Xiong *et al.*, 2017).

Table 5 Removal of organic pollutants by biochar derived from different feedstocks and pyrolysis temperatures

Chemicals	Examples
Organic pollutants include agrochemicals	Pesticides, herbicides, fungicide, insecticides include carbofuran, chlorpyrifos, atrazine, simazine, pyrimethanil etc., Phenol, Deisopropylatrazine
Antibiotics or drugs	e.g., sulfamethazine, sulfamethoxazole, tylosine, acetaminophen, ibuprofen, tetracycline etc., Acetaminophen, Ibuprofen, Naproxen, Sulfamethazine,
Industrial chemicals including polycyclic aromatic hydrocarbons	e.g., naphthalene, phenanthrene, pyrene, anthracene, polychlorinated biphenyl, m-dinitrobenzene, catechol, p-nitrotoluene etc.
Volatile organic compounds (VOCs)	e.g., trichloroethylene, benzene, furan, butanol, hexane etc
Cationic aromatic dyes	e.g., rhodanine, brilliant-blue, methyl-violet, methyleneblue etc.
Aromatic cationic dyes	Methylene blue, Methyl violet,
Polycyclic aromatic hydrocarbons	N-nitrosodi-methylamine, Naphthalene, Naphthenic acids, Nonylphenol, Phenanthrene
Miscellaneous pollutants	Furans (Furfural, HMF) inorganic pollutants (e.g., Pb ²⁺ , Cu ²⁺ , Cd ²⁺ , Zn ²⁺ , Hg ²⁺ and Ni ²⁺ , H ₂ S, NH ₃ , NH ₄ ⁺ , NO ₃ ⁻ , Cr ₃ ⁺ , Sb ₃ ⁺)

Catalysts have played a crucial role in developing technologies to convert not only conventional carbonaceous feedstocks (e.g., coal, natural gas, and petroleum) but also renewable feedstocks (e.g., biomass) into value-added products such as fuels and chemicals. The global catalyst market is estimated to be about \$34.3 billion by 2024 (The Global Catalyst Market, 2018), more than 35% of the global GDP was associated with catalytic technologies, and 95% of industrial products were estimated to be produced via catalytic processes. Given that biochar is a highly porous and carbon-rich material, biochar is a promising alternative to replace conventional solid carbon-based catalysts with some known demerits (e.g., expensiveness and environmentally unfriendliness). Various modification can be made for the biochar via acid/base treatment or carbonization to improve its physicochemical properties making it an excellent candidate for catalytic applications. Waste biomass has been increasingly targeted as a renewable feedstock for the production of fuels and more recently platform chemicals,

Biochar as Animal Feed

In addition to the use of biochar to improve soils and to sequester carbon, it can also be used as animal feed and other animal husbandry applications. Recent research results (Carlson and Hawkins, 2018) have shown that the addition of biochar to animal feed may have the potential to offer a number of invaluable benefits: improved digestion, increased immunity, reduced chronic botulism, increased feed, and energy efficiency, increased growth rates, reduced methane production.

Conclusion

The article covers the description of biomass waste-derived material, known as biochar and its physicochemical properties along with its proximate analysis. The potential biomass wastes that can be used for biochar production are presented. Various production routes of biochar have been discussed. Among those, pyrolysis, torrefaction, slow pyrolysis, intermediate pyrolysis, fast pyrolysis, flash pyrolysis, hydrothermal carbonization, and microwave assisted pyrolysis are discussed with their operating conditions and specifications. Biochars have a tremendous range of physical and chemical properties, which greatly affect their wide applications. The physical, chemical and mechanical properties of biochars depend on the feedstock type and pyrolysis operating conditions. The feedstock and the method by which the biochar is produced has a significant impact on biochar characteristics, including concentrations of elemental constituents, density, porosity, and pH, which collectively impact the ability of the biochar for various applications. Slow pyrolysis process is the most suitable process for biochar production. The most common areas of application of biochar are also presented especially in the removal of organic contaminants and heavy metals from waste effluents. The main applications of the biochar are as an adsorbent, as a catalyst and catalyst support. The quality of biochar for various applications are discussed along with different quality parameters.

Introduction

Poly-lactic-acid (PLA) is one of the thermoplastic polymer classes which have turned into a “material of decision” in bio-medical applications or biomedical surgery’s for its capacity to satisfy difficult needs that normally incorporate some special features like: bio-compatibility, bio-degradability, mechanical quality and process ability. In spite of the upsides of unadulterated PLA in a more extensive range of utilizations, it is constrained by its hydrophobicity, with slow bio-degradability and low impact toughness. The bio-degradable polymers have upper hand in polymer field, because of its versatility. PLA is industrially accessible bio-based polymer utilized as a part of an assortment of utilizations because of its high quality modulus and bio-degradability (Conn *et al.*, 1995). It is a thermo-plastic polymer having a place with the α -hydroxy acidic group. The polymer is then blended by coordinate poly-condensation of lactic corrosive utilizing an appropriate impetus (Södergård and Stolt, 2002; Chanfreau *et al.*, 2010; Omay and Guvenilir, 2013). Because of the nearness of two stereo isomers of lactic corrosive, PLA can be integrated as PDLA, PLLA or PDLLA. The two unadulterated homo-polymers and a variety of PDLLA polymers with changing proportions exhibit a scope of thermal, mechanical, internal as well as external properties (Zeng *et al.*, 2015; Zhang and Wang, 2008). PLA has poor tensile properties, low utilization temperature and a comparatively little window for process-ability. The vast majority of the monetarily accessible PLA involves for the most part of PLLA and very less amount of PDLA was mixed to expand the preparing window by instigating liquefying point misery. That causes a significant abatement in crystallinity (Garlotta, 2001). The chitosan (CS) and PLA have got the consideration by researchers as bio-degradable and bio-compatible materials (Zheng and Cui, 2010; Meng *et al.*, 2010; Bi *et al.*, 2011). The CS needs to be dissolved in weaken acidic arrangement, and as a framework/scaffolds material. CS decays gradually, and can’t coordinate with recovery of tissues. Additionally, CS’s mechanical properties are somewhat poor (Chen *et al.*, 2006; Lin and Yeh, 2010; Lee *et al.*, 2010; Fan *et al.*, 2010). These properties confine CS’s significantly for more extensive application in tissue designing. PLA polymers are the most broadly utilized manufactured bio-degradable macro-molecule, with matchless properties and process capacity. In addition, PLA’s degradation rate is customizable. In this manner, CS and PLA can be seen as complimentary in their qualities as tissue building materials. CS can counterbalance the acidic degradation produced by PLA, while, CS’s mechanical properties could be enhanced (Rasal *et al.*, 2010). Bone comprises of 69% (by weight) calcium phosphate, 21% (by weight) collagen, 9% (by weight) water and 1% (by weight) different constituents. It has a composite nature, which is developed of predominantly fired HAp and polymer with a complex various leveled micro-structure exceptionally hard to mimic which gives a large portion of the better mechanical properties than bone. Table 1 shows required mechanical properties of compact bone.

The current advancements in simulated bone territory incorporate earthenware production (ceramics), which are bio-insert substances, for example, alumina and zirconia, resorbable as a tri (calcium phosphate), and bio-active materials such as HAp. Different phases of calcium phosphate ceramics are used depending upon whether a resorbable or bio-active material is required. Numerous applications in hard tissue were chronicled before. A portion of the illustrations are swaps for teeth, hips, ligament and tendons and regeneration for periodontal sickness, maxilla facial remaking, enlargement and adjustment of the jaw bone, spinal combination and bone repair after tumour medical procedure. The tissue connection/bonding with

Table 1 Required mechanical properties of compact bone

Properties	Direction of test	
	Parallel	Normal
Young’s modulus	17.0–18.9 GPa	11.5 GPa
Bending strength	160 MPa	–
Tensile strength	124–174 MPa	49 MPa
Shear strength	54 MPa	–
Compressive strength	170–193 MPa	133 MPa
Yield compressive strain	0.010	0.011
Ultimate tensile strain	0.014–0.031	0.007
Yield tensile strain	0.007	0.004

earthenware production (ceramics) and delicate tissues other than the hard tissue can be seen utilizing bio-active ceramics (Liou and Chen, 2002; Dorozhkin, 2009a; Zhang and Zhang, 2001; Kwon *et al.*, 2003). Bio-materials, for example CS, HAp, beta-tricalcium phosphate have noteworthy applications for bone substitution. Their applications incorporate, for instance, prostheses for substitution, materials covering or support in parts of the implants/scaffolds. The most widely recognized bio-material utilized as a part of the previous decades in hard tissue recovery is HAp, since it is the major inorganic compound in mammalian hard tissue and is profoundly perceived and utilized for its bio-compatibility, not costly and plentiful. It has been fused into a wide assortment of bio-medical gadgets including dental inserts, bio-degradable scaffolds, and different sorts of orthopedic embeds in various parts of the skeleton. (Fujita *et al.*, 2003; Kwon *et al.*, 2003; Dorozhkin, 2009b; Combes and Rey, 2010; Zhang and Zhang, 2001). HAp has been broadly utilized because of its compound likeness to bone and great bio similarity in the physiological ecological and a similarity with synthetic and characteristic polymers as poly-saccharides and additionally proteins making a useful bio-material for therapeutic and bio-medical application. HAp stimulates osteo conduction and can be coordinated into bone without inciting an insusceptible response. The basic arrangement of HAp is straightforwardly related with the organic reaction of inserts, affected by variables, for example, size and morphology of the particles inside the manufactured platform, and has been basic in permitting osteo conduction and bone development into the scaffolds permeable while additionally permitting the exchange of supplements through the scaffolds (Muzzarelli, 2011; Muzzarelli and Muzzarelli, 2002; Dorozhkin, 2009b; Pramanik *et al.*, 2009; Wilson and Hull, 2008). The challenge of hard tissue engineering is to develop a suitable bone scaffold with sufficient porosity and mechanical strength to allow cell adhesion, migration, growth and proliferation resulting in good integration with surrounding tissues. The quantity of materials has been utilized for bone tissue engineering including natural polymers, bio-glass and ceramics as like HAp. Surface with a positive charge elevates cell grip because of its negative charge; it can artificially bond with decidedly charged poly-saccharides as well as HAp with negative charge like proteins or potentially another calcium phosphate, for example, – tenocyclidine (TCP), shaping a more grounded platform material (Chen *et al.*, 2006; Dorozhkin, 2009a; Swetha *et al.*, 2010; Muzzarelli, 2011).

In this article, an effort has been made to develop the 3D scaffolds/implants on FDM by using in-house developed bio-compatible/bio-degradable feedstock filament (FDM wire) comprising of PLA, CS and HAp as a case study. Initially five input parameters (namely: material composition, rotational speed, barrel temperature, HAp particle size, and applied load) were judiciously selected for fabrication of FDM input wire. The wires having better flowability and suitable mechanical and dimensional properties have been used on the FDM machine.

Properties of PLA Mixed With Polymers/Composites

In spite of being a material with high quality and modulus, PLA needs application in mechanically requesting conditions because of low effect durability, fragile nature and low break elongation. Table 2 lists the different properties (thermal, mechanical and tensile) of the PLA (Mark, 1999).

In the meantime, PLA mix with different polymers with less strength can improve the polymers modulus and its rigidity with mediocre properties. Subsequently, PLA is regularly mixed with different polymers to upgrade thermo-mechanical properties for both polymeric materials (PLA and other). The alteration of thermal behavior in PLA blends is dictated by the extent of miscibility of the constituent polymers. Polymer mixes can be custom fitted by changing the polymer arrangement to accomplish a blend of mechanical and thermal properties as required for particular applications. The impact of liquefy mixing PLA and PMMA to locate a solitary T_g for the mixes subsequent to warming them to 250°C out of a DSC crucible, with an intermediary to those for individual polymers and effect of durability like the perfect polymer in which they were rich (Anakabe *et al.*, 2015). Jing *et al.* (2015) concluded the impact of handling temperature on the last T_g of the mix since they watched that the mixes prepared at 215°C portrayed double T_g changes because of polymer immiscibility beneath the UCST of 230°C. In another investigation, mixing PLA with thermo-plastic poly-urethane (TPU) upgraded sturdiness and break elongation of PLA, granted by TPU. They additionally noticed that mix with 80% PLA (by weight) has shape memory behavior, which the authors ascribe to the crystalline locales of PLA, causing maintenance of shape by going about as cross-linking focuses in the mixing/blending. Poly ϵ -capro-lactone (PCL) has additionally been describe to build the break elongation and thermal steadiness for PLA in a mix, joined by an abatement in the rigidity and modulus contrasted with flawless PLA because of the lower estimations of these properties in PCL (Ferri *et al.*, 2016; Yang *et al.*, 2015). The addition of PCL also changes the failure properties of the

Table 2 Thermal, mechanical and tensile properties of PLA polymers

Crystallinity	Semi crystalline, 0%–37%, Amorphous
Young's Modulus	1.2–3 GPa
Melting Temperature (T_m)	145–186°C
Glass transition Temperature (T_g)	50–64°C
Elongation at break	2%–6%
Tensile Strength	28–50 MPa

Note: Mark, J.E., 1999. Poly (lactic acid), In: Mark, J.E. (Ed.) Polymer Data Handbook. New York: Oxford University Press, pp. 627–633.

blend from brittle, as in case of pure PLA, to ductile. As specified before, PLA is mixed with pure polymers with lower mechanical strength for improvement of their different properties (such as tensile and thermal). Starch/PLA mixture have been reported where PLA improve the mechanical and tensile properties of the mixture (Shirai *et al.*, 2013b; Preechawong *et al.*, 2005; Shirai *et al.*, 2013a; Wootthikanokkhan *et al.*, 2012). PLA-PCL mixtures, shows improvement in mechanical and tensile properties, break elongation, Young's modulus and hardness with an increment of PLA quantity from 60% to 80% (Zhao and Zhao, 2016). Blended PLA with soya protein results in to increase in tensile properties, which is further improved by the mixing of poly-2-ethyl-2-oxazoline as a compatibilizing agent (Zhang *et al.*, 2006).

Mechanical Properties of Hard Tissues, Soft Tissues, Metallic/Ceramic/Polymeric Biomaterials

Figs. 1–5 showed mechanical properties of hard tissues, soft tissues, metallic biomaterials, ceramic biomaterials and polymeric biomaterials.

In polymer small amount of compatibilizers are mixed/blends to expand the internal bond between polymers, which thusly enhances the different properties of composition of polymeric materials. It exhibit a nitty gritty survey utilization/applications of compatibilization in the mixes of bio-degradable polymers (Imre and Pukánszky, 2013; Yu *et al.*, 2011). The utilization of different compatibilizers has been investigated to enhance the PLA properties mixes with different polymers, which the creators credit to starch going about as a nucleating operator for PLA.

Subsequently the interfaces between two polymers are made strides. In light of the coveted application, polymers are regularly subjected to plasticization to make the material more adaptable. Plasticizers actuate a lessening in T_g , rigidity and arrangement thickness of the polymer, yet increment its extension, affect strength and process ability (Wypych, 2012). In literature review it has been reported that for improvement/enhancement of polymers properties only PLA was mixed with plasticizers polymer and the

presentation of plasticizers in mixes of PLA with different polymers, either to make them more process able or to additionally enhance properties. It was also reported that for improvement/enhancements of PLA adaptability and different properties (mechanical and tensile) PEG and PEG subordinates or co-polymers are main plasticizers (Sungsanit *et al.*, 2012; Park *et al.*, 2012; Zubrowska *et al.*, 2015; Jia *et al.*, 2009).

As observed from Fig. 5 different thermoplastics have wide range of modulus and tensile strength, so one can select a particular or combination of thermoplastics (based upon compatibility) for tailor made applications.

Bio-Degradability of PLA

The reported literature highlights numerous applications of PLA, including biomedical, compostable bundling (because of its bio-degradable nature). Mixed PLA with different polymers creates another debasement profile that relies upon the measure of every polymer in the mix and also mixes morphology. The degradation rate of scaffolds results of every polymer continue as before as parent polymers, however the rate and level of debasement of the mix is managed by its structure and morphology. In this way, the debasement profile of a mix can be tuned by modifying its creation and handling conditions to suit the requirements of various applications. The bio-degradation of mixes is in simulated compost conditions for 70 days of PLA with TPU at increased temperature of 58°C (Jaso *et al.*, 2015). They found that rate of decaying of PLA mixes is managed by the polymer. They report that the mixes rich in TPU demonstrate quick introductory decaying took after by a level stage, like flawless TPU, which experienced quick beginning debasement, took after by a moderate debasement and just 30% mineralization toward the finish of 70 days. Conversely, the mixes rich in PLA display an underlying slack in debasement, yet accomplish a higher level of decaying toward the end. This is like unadulterated PLA, which begins to degrade following 20 days and is totally debased before 70 days' over. The authors noted that morphology assumes a vital part in the decaying procedure in which co-constant mixes degrading at a higher rate at first contrasted with those with globular morphology.

Notwithstanding mix synthesis and stage scattering, facilitate thermal handling of mixes and the presentation of added substances can dramatically affect the rate of decaying of a mix. Enzymatic decaying of PLA/PBST mixes in Tris HCl support with Proteinase K (Malwela and Ray, 2015). They report an improved decaying rate of the mix contrasted with the individual polymers because of stage isolated morphology of the mix, inferable from immiscibility of PLA and PBST. Strengthening the PLA/PBST films at 70°C decelerates the decaying rate because of the expanded crystallinity of the PBST stage and is additionally diminished by option of nano-clay fillers which upgrades the crystallinity of PBST. Debasement is much more drastically decelerated when the movies are strengthened at 120°C and soon there-after the crystallinity of the PLA stage is improved. This is additionally articulated by the option of nano-clay. Decaying of PLA under anatomical conditions for bio-medical applications is all around prove and has been widely announced and assessed (Saini *et al.*, 2016; Shasteen and Choy, 2011; Tsuji, 2005). An essential plan thought to accomplish ideal execution in-vivo for the finished result is to keep up the debasement of PLA mixes inside the anatomical imperatives, while tuning the decaying profile for particular biomedical applications, similar to tranquilize conveyance and platforms. Tuning the mix piece changes the rate of decayed, as well as adjusts the example to enable the material to degrade in an unpredictable manner. This can be especially useful to configuration discharge profiles for medicate conveyance applications and compatibilize scaffolds/implants decaying to tissue recuperation in tissue building or implants/transplant applications (Vieira *et al.*, 2015; Cai *et al.*, 2002; Kim *et al.*, 2005). PLA mixes with at least one polymer or co-polymers can yield complex degradation designs, which may not be conceivable on account of co-polymers alone, as PLGA, which, in spite of having a digressed decaying profile from source polymers, experience a foreordained decaying profile. For example, Zhu *et al.* (2015) built up a tissue designing platform utilizing a mix of PLA, PEG and a PLA-PEG co-polymer which demonstrate an underlying quick misfortune in reenacted physiological conditions, trailed by a moderate degradation at-least 100 h. This is speedier than the degradation for a flawless PLA platform indicating altogether slower degradation at-least 200 h. The creators likewise contrasted the degradation design with a PLA/PEG double which demonstrates an underlying quick degradation rate because of PEG disintegration took after by the degrading rate like pure PLA. Antimicrobial films fabricated from chitosan/starch/PLA mix by film extrusion utilizing a TSE. Starch gives hydro-philicity to the mix to encourage dissemination of water and starting burst arrival of chitosan, while the moderate degradation rate of PLA keeps up maintained discharge over a more extended time (Bie *et al.*, 2013). Another way to deal with plan bio-degradable films of PLA mixes with thermo-plastic starch and PBAT utilizing blown-film extrusion process. PLA, in these mixes, adds to the improvement of the modulus, quality and hindrance properties of the films, however it diminishes transparency and tensile properties as-like break elongation at more weight percentage (Shirai *et al.*, 2013b).

Fabrication of Bio-Compatible 3D Printed Scaffolds – A Case Study

This case study was conducted in manufacturing research lab (Production Engineering) at Guru Nanak Dev Engineering College, Ludhiana, India (Singh and Ranjan, 2017). An effort has been made to build 3D scaffolds on FDM by using in-house developed bio-compatible FDM wire (Ø 1.50–1.75 mm) by mixing of PVC, PP, and HAp. During pilot experimentation, an effort has been made to prepare the feed stock filament of biocompatible grade of PVC and PP in the ratio of 70:30 (by weight). The first step was to check the possibility of preparation of feed stock filament of PVC and PP, which is reinforced with HAp with varying

input parameters. Taking random selection of different composition/proportions of polymer materials, the best parametric condition or range of parametric condition was established for TSE. Table 3 shows list of input parameters and their levels for the experimental study.

Based upon Tables 3 and 4 shows the control log of experimentation based upon Taguchi L18 orthogonal array (O.A). After successful runs as per Table 4 output as peak Load and Young's Modulus have been recorded while tensile testing on universal testing machine.

As observed from Table 4, experimentation run No. 09 has the maximum value of peak load, as well as Young's Modulus in which parametric conditions are a combination of materials, are 96X + 4 at 50 rpm and the temperature was 200°C with the HAp grain size is 53 µm with a load applied as 20 kg. Further in experimentation run No. 13 was minimum value of peak load as well as Young's modulus in which the parametric conditions are combination of materials are 92X + 8 at 40 rpm and temperature was 190°C with 150 µm of HAp grain size and load applied was 10 kg.

After establishing mechanical properties the finally prepared feed stock filament at best settings were investigated for thermal properties on differential scanning calorimetry (DSC) setup. The sample filament wire prepared for experiment run 9 and 13 were subjected to DSC analysis. For thermal analysis METTLER TOLEDO, Model DSC3, Swiss make with (SW 14.00) software was used in N₂ gas environment. Figs. 6 and 7 shows the thermal analysis of feed stock filament run 9 (with better mechanical properties) and run 13 (with poor mechanical properties) respectively. As shown in Fig. 6, for thermal analysis 2 heating-cooling cycles are involved. In first cycle, initially heat the sample with comparison to reference from 30°C to 220°C at the rate of 10 K/min, after that in the presence of N₂ gas (flow rate is 50.0 ml/min) cooling process is done in which matter was cooled from 220°C to 30°C at the rate of 10 K/min. After that in the second cycle, same process was repeated. The maximum temperature is taken 220°C because of the material was burnt near 230°C and lower temperature is generally taken as near to room temperature. Fig. 7 shows thermal analysis of sample wire run-13. While comparing Figs. 6 and 7 it has been observed that melting point temperature (T_m) of run-9 was 160.29°C and for run-13 was 156.61°C and solidification temperature at 116.45°C in the first case and 114.63°C in second

15	92X + 8	40	200	53	15	14.20	111.37
16	92X + 8	50	180	150	15	17.10	136.57
17	92X + 8	50	190	53	20	16.10	128.64
18	92X + 8	50	200	106	10	20.12	161.37

case. Further it should be noted that the heat capacity (which is difference of heat input and released) for sample prepared at run-9 has dramatically increased after second repetition of heating-cooling cycle as compared to sample prepared at run-13, which justifies the use of parametric settings suggested for run-9 (as per Table 3).

The SEM analysis was conducted on the fractured surfaces of the samples (feed-stock filament of FDM wire). The micro-photographs suggest that the feed-stock filament have uniformly fibrous and open porous structure (see Fig. 8), which are sufficiently good for growth of cells and are suitable in bio-medical application. The porous structure of an implant provides channels for bone ingrowth. Porous materials have been introduced to obtain biological fixation and improve longevity of

Fig. 6 Thermograph of best feed stock filament according to mechanical properties (as per Table 4, run-9).

Fig. 7 Thermograph of poorest feedstock filament according to mechanical properties (as per Table 4, run-13).

Fig. 8 Microphotographs of the biocompatible feed stock filament taken on SEM.

orthopedic implants. Due to several clinically important disadvantages of dense biomaterials (metallic/polymeric), such as a high value of elasticity modulus, the fabrication of porous structures by powder metallurgy, foaming technologies, as well as AM methods have been widely developed in the last decades to overcome the limitations. In addition, porosity enhances the biological interlock between implant and bone.

Conclusions

In this article a case study for 3D printing of bio-compatible thermoplastic blended with HAp and CS has been presented. The composite based feed stock filament for FDM has been successfully prepared by using TSE. Following are the conclusions from this study:

- The biocompatible polymeric composites comprising of PVC-PP-HAp were prepared successfully with TSE in form of feed stock filament. The filament so prepared is ready to be used on commercial FDM setup without any change in any hardware/software of the system.
- For better understanding mechanical and thermal properties of PVC, PP with HAp reinforcement thermal analysis has been reported. It has been observed that polymeric composite material with composition/proportion as 96% polymer matrix (comprising of 70% of PVC and 30% of PP) and filler (HAp) as 4% (with grain size 53 μm) at 200°C processing temperature and rotational speed of 50 rpm with load applied of 20 kg on TSE are the best parametric conditions observed in this case study (from thermal stability and mechanical properties view point).
- Based upon SEM analysis it has been ascertained that the specimens/functional prototype prepared are structurally good and suitable for repair/regeneration of bone/fractured bone because the internal structure of the sample is fibrous, open and porous.

Introduction

The trend of renewed interest in natural materials has increased tremendously as researchers and scientists have focused on utilizing the natural materials for replacing the existing synthetic materials. The reason behind this phenomenon is due to ecological concern; the recyclability and environmental safety are becoming crucial for the introduction of new materials and products. Currently, researchers are moving towards combining natural and synthetic material. This is due to the fact that utilization of natural fiber based lignocellulose can be considered as interesting. Natural fibers such as kenaf, jute flax, hemp, oil empty fruit bunch (EFB), sisal, and sugar palm have shown economic and ecological advantages over synthetic fibers. The inferior properties of natural fiber such as physical, mechanical, and thermal properties have motivated a number of industrial sectors especially in the automotive sector to use these fibers as potential candidates in environmentally safe products.

Natural fibers could replace synthetic fibers in various applications. They are renewable, abundant, cheap, recyclable, and biodegradable, and have lower density and are less environmentally harmful compared with synthetic fiber. Nevertheless, the challenges of using these natural fibers, such as high water uptake and low mechanical properties as compared with synthetic fiber, limit its applications. To overcome this problem, many researchers have approached surface modification of fiber (Masudul Hassan and Wagner, 2016). Based on the studies shown, the treatment of fiber diminishes the water uptake and leads to high mechanical properties. Moreover, some researchers have studied the combination of synthetic and natural fiber to improve the performance of the composites. In this paper, the previous research on hybrid composites properties and method to improve the interfacial control between the fiber and matrix through experimental and morphology is discussed.

Hybrid Composites

The incorporation of natural fibers such as kenaf, sisal, jute, flax, and sugar palm fiber with synthetic fiber has gained increasing applications in many areas of technology and engineering. Hybridization of natural fiber with stronger and more corrosion resistant synthetic fiber such as carbon fiber can also enhance the stiffness, strength, as well as moisture resistant properties of the hybrid composites. Hybrid composites that contain two or more types of different fibers could complement what is lacking in the other properties. As a consequence, a balance in the performance of the hybrid composites could be achieved.

Mechanical Properties of Hybrid Thermoplastic Composites

It is well known that the composite properties highly depend on the individual reinforcements like the type of fiber, fiber architecture, and chemical composition of fiber, type of matrix, and fiber–matrix adhesion. Studies on the hybrid thermoplastic composites were carried out with both the natural fiber and synthetic fibers in the short and randomly oriented form (SFRP) and long fiber and mat form as preregs (LFRP).

Short and randomly oriented form composites

The SFRP composite consists of short and randomly oriented fiber reinforcements within the thermoplastic matrix. The chopped fibers are usually taken in a fixed proportion and mixed with thermoplastic resin (in the form of pellets) in a melt mixer to obtain the fiber/matrix mixture. The fiber/matrix mixture gets collected as chunks at the end of the mixing process. These can be used directly or further crushed into small pieces and fabricated using different techniques like hot press molding, pultrusion, and injection molding to form the composite.

Works on the SFRP composites were easy to find and have been studied widely by researchers with different fibers and various thermoplastic resins. This is due to their simplicity in production, cost saving in terms of fabric production, and reduced wastage of fiber due to their use in smaller size as microfibers or powder form. The most commonly identifiable hybrid composite with the short fibers constitutes two or more different fibers within a single matrix.

Increasing the overall fiber loading of jute/coir (mixed in a constant proportion at 1:1 ratio) in polypropylene (PP) matrix resulted in lower tensile strength, superior stiffness, flexural strength and modulus, and impact strength as shown in Fig. 1. Further variants were obtained by mixing jute/coir in different ratio or proportions such as 25:75, 50:50, and 75:25 in terms of fiber weight % while the overall fiber loading and matrix weight% were kept constant. Significant variation in strength and modulus were achieved as shown in Fig. 1 as a result of varying the individual fiber loading in the overall fiber loading (Siddika *et al.*, 2014).

Fig. 1 Mechanical properties of jute/coir reinforced polypropylene composites. (a) Tensile strength, (b) tensile modulus, (c) flexural strength, (d) flexural modulus, (e) impact strength. Reproduced from Siddika, S., Mansura, F., Hasan, M., Hassan, A., 2014. Effect of reinforcement and chemical treatment of fiber on the properties of jute-coir fiber reinforced hybrid polypropylene composites. *Fibers and Polymers* 15 (5), 1023–1028.

Similar variation in tensile, flexural, and impact strength due to the increment of overall fiber loading of hybrid sisal/banana fibers in poly(lactic) acid (PLA) matrix was reported by [Ranjan et al. \(2013\)](#). The composites with higher fiber loading exhibited a drop in strength. According to the authors ([Ranjan et al., 2013](#)), the weak interfacial adhesion between the natural fibers and PLA matrix as evident from the micrographs of the fractured specimen (refer to [Fig. 2](#)) was the primary reason for the lower strength of the hybrid composites.

[Arifuzzaman Khan et al. \(2013\)](#) highlighted that the mechanical properties of the banana/coir/Low density poly ethylene (LDPE) composite can be modified by increasing coir content in the fiber loading. Their results showed that optimum strength and modulus under the different mechanical loads occurred at different weight% (refer to [Fig. 3](#)). For instance, 15% coir fiber weight displayed best impact strength for the hybrid composites while 10% fiber weight showed best strength and modulus under the tensile and flexural load. Similar inferences on improvement in the impact strength were highlighted by [Pérez-Fonseca et al. \(2014\)](#)

on increasing coir content on the agave/coir/polyethylene hybrid composites (Pérez-Fonseca *et al.*, 2016). The general theory behind the superior impact strength for hybrid composites on increasing the coir content is due to the following reasons (1) higher amount of energy required to cause fiber pull-out and breakage at larger fiber loading and (2) lignocellulosic contents and elongation at break% of the individual fibers. On the other hand, difficulty in maintaining homogenous fiber dispersion at higher fiber loading, which causes agglomeration regions within the composite was responsible for lower strength and modulus at higher fiber loading (Kakou *et al.*, 2015). These sites act as stress concentration regions on the application of load due to the higher fiber-fiber interaction. This, in turn, leads to crack initiation followed by the final failure (Hassan *et al.*, 2011).

The main drawback of using natural fibers is their inferior strength, hydrophilic nature due to the presence of lignocellulosic contents, and weak interfacial adhesion with the hydrophobic matrix. Efforts have been taken by researchers to improve the performance of hybrid composites with the natural fibers through the following ways:

- Introducing synthetic reinforcements
- Fiber treatments
- Introducing fillers or coupling agents like maleic anhydrides (MA)

Synthetic reinforcements

Ground glass and carbon fibers from the fabric were individually used as reinforcements with sisal and their fiber weight was varied in the ratios of 25:75, 50:50, and 75:25 in the PP matrix. Best mechanical properties were achieved with sisal:glass and sisal:carbon at 25:75 ratio and further increase of the sisal content only led to drop in the strength and modulus. Nearly equivalent performance under the tensile, flexural, and impact loads achieved by composite at 50:50 ratio by sisal:glass highlights that dependency on the less environment-friendly synthetic fibers can be substituted by the natural fibers (Aslan *et al.*, 2018). Ashori *et al.* (2014) introduced 10% and 15% fiber weight glass fibers in the overall 50% fiber loading of bagasse/PP and corn stalk/PP composites. Maximum strength and modulus was observed with 10% while further increase of glass fiber weight to 15% resulted in lower mechanical properties than the former. This behavior at higher fiber loading was caused by the agglomeration of glass fibers leading to lower mechanical properties. On the other hand, corn stalk/glass fibers/PP was able to perform better under mechanical loads than the former due to the higher fiber aspect ratio (fiber length/width) compared with bagasse fibers. This implies that the higher fiber aspect ratio enabled better stress transfer between the fiber and matrix, thereby imparting superior mechanical properties.

Fiber treatments

One of the important reasons for lower mechanical properties of the hybrid composites reinforced with natural fibers is their poor wettability with the hydrophobic matrix. The smoother surface of the natural fiber was modified by subjecting the fiber to different chemical treatments. The commonly used chemical treatments include mercerization with alkali, bleaching, silane, acetylation, etc. The mechanism responsible for improved fiber–matrix adhesion is unique to each chemical treatment. Alkali treatment of the fiber creates rougher fiber surface and leads to fibrillation due to the removal of hemicellulose, lignin, pectin, waxes, and other impurities. The rougher surface and fibrillation permits better mechanical interlocking with the matrix (Chandrasekar *et al.*, 2017). In case of acetylation, presence of $-\text{CH}_3$ groups in the treated fiber enables better wetting with the matrix while bleaching facilitates fibrillation in the fiber surface due to the removal of hemicellulose and lignin (Arifuzzaman Khan *et al.*, 2013).

Atiqah *et al.* (2017) showed that tensile, flexural, and impact properties of the sugar palm/glass/polyurethane composite can be improved by using the 6 wt% sodium hydroxide (NaOH), 2 wt% silane and combined NaOH–silane treated sugar palm fibers. The highest improvement in properties was observed for the combined treatment. This is due to the fact that NaOH treatment creates rough fiber surface while the silane treatment creates silanol groups, which bond with the hydroxyl group of the fiber and lead to stronger fiber–matrix interface (Goriparthi *et al.*, 2012). However, the fiber treatments have limitations too. The improvement in mechanical properties was dependent on the fiber treatment conditions like chemical concentration and immersion time. Jute/coir/PP composites demonstrated better strength and modulus when reinforced with 5% NaOH treated fibers while inferior strength and modulus at 10% NaOH for the same immersion time. The inferior behavior at greater chemical concentration is due to higher degree of fibrillation caused by the excess removal of hemicellulose, lignin, etc. (Siddika *et al.*, 2014). In this case, fibers become brittle, weaker, and ineffective in stress transfer causing premature failure at lower loads. Another advantage of using treated fibers in the composite is their reduced water uptake and moderate loss in strength and stiffness after moisture absorption. Wood flour/wheat husk/PP hybrid composite with NaOH and benzoyl chloride treated fibers was conditioned in the water bath at room temperature for 192 h. The conditioned composites showed lower drop in strength and modulus than the composites with untreated fibers (Upadhyaya *et al.*, 2012).

Fillers

Fillers are additives added in a small quantity to the matrix for enhancing the mechanical properties of the composite. Similar to fiber treatments, the filler concentration and dispersion within the matrix governs the improvement in the properties. From the literature, it was found that MA was the most frequently used filler in the thermoplastic composites. Other than enhancing the mechanical properties, MA was also effective in restricting the water uptake and preventing composite degradation as reflected by the reduced loss in strength and modulus in comparison to the composites without fillers from their research (Pérez-Fonseca *et al.*, 2016). Fillers like aluminum hydroxide, magnesium hydroxide, hydrotalcite, and calcium sulfate dihydrate have superior thermal insulation properties and can be added to the composite to be used for the high temperature applications and materials requiring flammability resistance (Pearce, 2012).

Short and Randomly Oriented Form Composites With Thermoplastic Blends

The variants in the hybrid composites with two or more fibers in a single matrix seen in the previous section were found to have limitations such as weaker fiber–matrix compatibility, fiber agglomeration due to poor fiber dispersion at higher fiber loading and difference in the fiber aspect ratio influencing the mechanical properties. To avoid these problems, hybrid composites with two different thermoplastic blends reinforced with single fiber were proposed and their properties were explored. Table 1 represents some of the thermoplastic blend combinations used by researchers in their research.

Tensile strength was found to decrease with the increase in fiber content of the polyvinyl chloride/thermoplastic polyurethane/kenaf hybrid composite while the impact strength and modulus showed increasing trend with the fiber loading (El-Shekeil *et al.*, 2014). Teixeira *et al.* (2012) studied the influence of cassava starch content (thermoplastic starch (TPS)) in cassava bagasse/PLA/TPS with constant fiber loading. Their results indicate that tensile strength and modulus decrease with the increase in TPS content. According to

Table 1 Hybrid composites based on the thermoplastic blends from the previous studies

Composite	Fabrication method	Resin weight	Fiber weight	References
PVC/TPU/Kenaf (PVC:TPU::1:4 ratio)	Compression molding	60%–80%	20%–40%	El-Shekeil <i>et al.</i> (2014)
PP/PLA/eucalyptus wood flour	Compression molding	2% MAPP 83% PP/PLA blend	15%	Darie <i>et al.</i> (2013)
HDPE/SBR/Flax/SEBS-g-MA	Injection molding	0%–30%	0%–30%	Kakroodi <i>et al.</i> (2012)

Abbreviations: HDPE, high density poly ethylene; MAPP, maleic anhydride grafted polypropylene; PLA, poly(lactic) acid; PP, polypropylene; PVC, polyvinyl chloride; SBR, styrene butadiene rubber; SEBS-g-MA, maleic anhydride grafted styrene-ethylene/butylene-styrene; TPU, thermoplastic polyurethane.

Darie *et al.* (2013) using the modified eucalyptus wood flour with the toluene-2,4-diisocyanate in the PP/maleic anhydride grafted polypropylene/PLA blend resulted in superior tensile strength, stiffness, and impact strength. Hybrid composite with the treated fibers showed greater resistance to accelerated weathering conditions as displayed by moderate loss in strength and stiffness in comparison to the hybrid composite with the untreated fibers. Kakroodi *et al.* (2012) fabricated the flax/high density poly ethylene/styrene butadiene rubber (SBR) with and without the styrene and ethylene/butylene with styrene content of 30% and 2% MA (maleic anhydride grafted styrene-ethylene/butylene-styrene). Optimum strength and modulus was achieved for the hybrid composite having 15 wt% of both the flax and SBR. Use of coupling agent helped the hybrid composites to have superior properties over the composites without coupling agent. Similar improvements in the tensile strength and modulus were reported by Majid *et al.* (2010) on the use of PE-g-MA coupling with the kenaf/LDPE/thermoplastic sago starch composite.

The SFRP composites are less desirable for high-performance applications. This is where the LFRP composites are preferred over the SFRP composite due to their high strength and stiffness characteristic. LFRP composites are also said to have higher impact strength due to their fiber structure, which requires higher energy to cause failure in the form of fiber pull-out after the impact (Dan-Mallam *et al.*, 2014).

Long Fiber and Mat Form as Prepregs Composites

LFRP composite are basically made of prepregs. Initially, the thermoplastic pellets were melted under temperature and pressure in a mold into thin sheets or films. Then, the sheets are placed on top and bottom of the fabric followed by pressing or melting with the temperature and pressure to form the prepregs. Two or more layers of such prepreg with different fabric reinforcements can be cured to form the LFRP composite. The advantages of using LFRP include superior mechanical properties due to the use of long fibers or fabric form.

Karaduman *et al.* (2015) studied the effect of stacking sequence of woven flax (W) and nonwoven jute (N) in PP matrix fabricated by the hot press molding. The hybrid composite WNNW with woven flax on the outer layer and jute as inner core displayed higher strength and modulus while the NWWN configuration exhibited maximum impact strength. Incorporation of 10 wt% glass fiber in the jute/PP (twisted yarn and untwisted yarn) yielded improvement in the tensile and flexural properties (Uawongsuwan *et al.*, 2015).

Dan-Mallam *et al.* (2014) fabricated hybrid composite with the kenaf/polyethylene terephthalate fiber based fabric prepreg in the woven interply and interwoven ply configurations. Interwoven hybrid composites outperformed woven interply hybrid composite in terms of the tensile and impact strength while the latter was found to possess greater flexural strength than the former. Polycopalactone (PCL) was blended with the PLA matrix and the PCL/PLA mixture along with unidirectional stitched jute fabric (Goriparthi *et al.*, 2012). Increasing PCL weight% led to improvement in toughness of the hybrid composite on the expense of tensile strength and modulus. Lower tensile properties on increasing the PCL content were attributed to the poor compatibility with the matrix and their inferior stiffness characteristic.

Many researchers have improved the interface adhesion by reducing the moisture absorption properties through fiber modification of the fiber. Nevertheless, to control the interface between fiber and matrix, layering sequence of the fibers is also important. Stacking of the woven fiber in the middle caused high bending stiffness that leads to larger delamination of composites. The method of fabrication and fiber treatment can influence the interfacial adhesion of matrix and fiber.

Mechanical Properties of Thermoset Hybrid Composites

In a thermoset polymer all the molecules are chemically joined by using cross-links, forming a rigid, three-dimensional network structure. As soon as the cross-links are combined during the curing reaction, the thermoset polymer cannot be melted by applying heat. Nevertheless, if the number of cross-links is lower, it could be possible to soften them at higher temperatures.

The main consideration when selecting a matrix is the basic mechanical properties. High tensile modulus, high tensile strength, and high fracture strength are the most desirable properties of the matrix for producing high-performance composites. All these properties influence the compressive strength, intraply cracking, ply delamination, and crack growth of their respective composites. Thermoset polymers (also known as resins) were traditionally used as fiber-reinforced composite matrix material. The starting materials used to polymerize a thermoset polymer are usually liquid chemicals with a low molecular weight and very low viscosity. Fibers are immersed in these chemicals before the polymerization begins. Furthermore, the viscosity of the polymer is lower at the

Table 2 Hybrid composites based on the thermoset blends from previous studies

Type of fiber and reinforcement	Matrix	Specification	References

Abbreviations: EFB, empty fruit bunch; KF, kenaf fiber; PALF, pineapple leaf fiber.

time of fiber immersion and can easily be wetted between the fibers and the matrix without the help of either high temperature or pressure. Thermoset polymers are highly thermal and chemical resistant. In addition, these polymers show lower creep and stress relaxation compared with the thermoplastic matrix. Hence, the thermoset matrix has been widely used to produce high-performance polymer matrix composites. Some important works on the thermoset based composites were tabulated in [Table 2](#). The thermoset matrix is reinforced by combining various natural fibers (sisal, banana, pineapple leaf, etc.) or by combining more synthetic fiber (glass, kevlar, carbon, etc.) or combining both natural and synthetic fibers. This section focuses the mechanical properties of hybrid composites made by natural–natural, natural–synthetic, and synthetic–synthetic fibers.

Natural–Natural

The influence of fiber loading on mechanical properties of chopped pineapple leaf fiber (PALF) and kenaf fiber (KF)/phenolic (PF) matrix composites was studied by [Asim *et al.* \(2018\)](#). The PALF/PF, KF/PF, and PALF/KF/PF composites were made by hot press molding technique and the fibers were controlled for 50% by weight in all composites. Various types of hybrid combinations were 35% PALF/15% KF, 25% PALF/25% KF, and 15% PALF/35% KF. Their analysis revealed that the addition of KF with PALF improved the mechanical properties. Among the composites, pure KF/PF composites showed the highest tensile and flexural strengths due to the good bonding and better compatibility between KF and PF. According to the fiber bundle theory, strong fiber (KF) can withstand higher loads and it holds the weaker fiber (PALF) and the matrix (PF). Hence the 15% PALF/35% KF exhibited higher tensile strain than the other types of composites. In case of impact properties, fiber content of PALF influenced the property. Hence the pure PALF/PF composites showed the highest value of impact resistance (7.05 kJ/m²) and energy absorption (63%). Among the hybrids, 35% PALF/15% KF composites exhibited the maximum impact properties. It was attributed to the higher aspect ratio and higher amounts of cellulose contents in PALF. Similar tensile and impact results were reported in [Masudul Hassan and Wagner \(2016\)](#), [Siddika *et al.* \(2014\)](#), [Ranjan *et al.* \(2013\)](#) and [Arifuzzaman Khan *et al.* \(2013\)](#).

[Adhikari and Gowda \(2017\)](#) analyzed the mechanical properties of banana/jute hybrid polyester composites fabricated by compression molding technique with controlled fiber volume fractions from 5% to 25% (increased by 5%), maintaining a 1:1 ratio; whereas the fiber length was maintained to 10 mm. Maximum tensile and flexural strengths were reached at 15% volume fraction at 25.21 MPa and 182.34 MPa respectively. But the impact strength was increased with increasing the fiber volume fractions until the maximum fiber volume fractions (until 25 wt%). Their respective impact strength was around 25 J/m.

For plant-based fiber composites, however, there is a limited interaction between hydrophilic fibers and matrix, which is usually hydrophobic. This leads to poor interface bonding that limits mechanical performance and low moisture resistance that affects long-term properties ([Pickering *et al.*, 2016](#)). Insufficient fiber wetting results in interface defects that can act as concentrations of stress ([Chen *et al.*, 2006](#)). It has been shown that fiber wettability affects the toughness, tensile strength, and flexural strength of composites ([Wu and Dzenis, 2006](#)). Chemical treatment can improve fiber wettability and thus improve the interfacial strength. Alkali, acetyl, silane, and maleated anhydride grafted coupling agent are the most popular, but enzyme treatment is becoming increasingly popular with particular environmental friendliness benefits ([Faruk *et al.*, 2014](#)). To improve the mechanical properties of the composites, PALF/KF fibers were silane treated (2% for 3 h) and the composites were analyzed for mechanical properties ([Asim *et al.*, 2017](#)). Due to the chemical treatment, the flexural and impact properties of hybrids were improved and the tensile strength declined when

increasing the fiber content of PALF in comparison to untreated hybrid composites. The treated PALF has effectively improved the mechanical strength such as flexural strength, modulus, impact strength, and energy absorption whereas the KF was helped to improve the tensile properties. The improvements after the silane treatment were attributed to the removal of lignin and hemicellulose from the surface of the fiber. Similar chemical treatments were reported in Maslinda *et al.* (2017), Kumar *et al.* (2014) and Narendar *et al.* (2016).

The properties of the composites are also affected by the so-called fiber architecture. Fiber architecture implies the use of fibers in various forms as unidirectional, woven structures, chopped strand mat, and 3D random arrangement.

Hanan *et al.* (2018) fabricated bilayer hybrid epoxy composites reinforced by oil palm EFB mat and nonwoven KF mat by hot press molding at 120°C. The different weight ratios of oil palm EFB and KF were 4:1, 1:1, and 1:4 and overall fiber loading was maintained 50% by weight in all the composites. Results showed that the tensile strength and the flexural strengths were more influenced by the addition of KF than the addition of oil palm EFB in hybrid composites. Further, the hybrid composites possessed higher tensile strength than the pure fiber composites (oil palm EFB and KF). Hence they concluded that strong fiber could be used as a skin layer for producing higher tensile properties. Further, the pure EFB composites exhibited lower tensile strength and flexural strength. It was attributed to interlaced EFB fiber bundles. According to Jawaid *et al.* (2013) due to the chemical composition of EFB (cellulose, hemicellulose, and lignin) and cell wall architecture, the oil palm composites exhibited higher impact strength. Chaudhary *et al.* (2018) also studied the mechanical properties of jute/hemp/flax hybrid epoxy composites. Amongst the studied configurations, the jute/hemp/flax/epoxy hybrid composites exhibited the highest tensile (58.59 MPa) and impact strength (10.19 kJ/m²). Jute/hemp/epoxy hybrid composites exhibited the highest flexural strength (86.6 MPa). All components, such as fiber and matrix, could act as a single unit against the flexural load, which in turn results from strong interfacial adhesion of the fiber/matrix interphase.

Natural fibers, however, have some disadvantages that limit their actual application, such as larger scatter in their properties, moisture absorption, and lower thermal stability (Di Landro and Lorenzi, 2009). The researchers, therefore, hybridize synthetic fibers with natural fibers to obtain higher strength and modulus.

Natural–Synthetic

Ahmad *et al.* (2018) analyzed the influence of moisture degradation on the mechanical properties of hybrid composites. These composites were fabricated by using different fibers, such as woven hemp (HH), woven PET (PP), and interwoven hemp/PET hybrid (HP). The HP composites exhibited higher tensile and flexural strengths in dry and wet conditions compared with HH and PP. The higher tensile strength of HP composites was due to orientating high strength fiber (hemp) along the fiber loading direction, whereas the flexural strength was found to be higher due to the type of fiber used (hemp or PET) in the warp and weft directions. Similar types of works were reported by Alavudeen *et al.* (2015) for kenaf/banana (mat form) polyester hybrid composites, whereas the mechanical properties were influenced by the direction of warp- and weft-oriented fibers.

Maslinda *et al.* (2017) also studied the effect of water absorption for interwoven kenaf/jute and kenaf/hemp hybrid epoxy composites and made by infusion technique. The different types of composites were woven kenaf/kenaf (KK), woven jute/jute (JJ), woven hemp/hemp (HH), interwoven kenaf/jute (KJ), and interwoven kenaf/hemp (KH). The interlocking structure between the fiber yarns obtained greater stress absorption of the interwoven hybrid composites; hence the interwoven hybrids need a greater load to break. Further, as a result of water absorption (in longer periods) it reduced the strength and modulus of the composites. However, due to a breakdown of the cellulose structure, the failure strain increased with increasing immersion time.

Raffia/glass/epoxy laminated hybrid composites were fabricated by compression molding technique and the effect of NaOH treatment of raffia fibers on flexural and Iosipescu shear properties was studied (Ouarhim *et al.*, 2018). The hybrid samples encompass three layers. The face sheets were fabricated of 1-mm-thick glass fibers, and the core includes treated or untreated raffia fibers of a thickness 2 mm. The proportion of raffia fibers was maintained higher than the glass fibers in all composites. The pure glass fiber composites gave higher flexural modulus (4 GPa) than the hybrid composites due to their intrinsic properties. However, the treated hybrid composites exhibited higher flexural modulus (3.6 GPa) than the untreated hybrid composites (3.4 GPa). The improvement was attributed to (1) the high load was effectively transmitted from fibers to the matrix during the loading conditions and (2) treated fibers allowed a higher amount of resin penetration, which helped to improve the fiber to matrix bonding and also prevented the detachment of fibers from the matrix.

Iosipescu shear test was used to understand the shear behavior of both isotropic and anisotropic solids, including (1) metals, (2) polymers, and (3) randomly fiber oriented composites. The results of Iosipescu shear stresses followed the same pattern as the flexural modulus of composites, in which addition of glass fiber with raffia fiber had the ability to produce higher shear strength (407.7 MPa) than the pure raffia fiber composites (109.4 MPa). As expected the treated hybrid composites exhibited higher shear strength (600.6 MPa) than the untreated hybrid composites (407.7 MPa).

Natural fibers have many advantages over synthetic fibers, such as reduced health risks, biodegradability and positive environmental impacts, etc. However, the natural fibers have several limitations such as lower tensile strength and they begin to degrade when the temperature exceeds 200°C. The degradation will lead to odor, volatile release, decoloration, and mechanical properties deterioration. The synthetic fiber possesses high tensile strength, high chemical resistance, excellent insulation properties, low cost (e.g., glass fiber), etc. Hence, the researchers hybridized by combining synthetic fibers together to produce higher strengths than the

natural–synthetic fiber composites. Moreover, the hybrid composites with synthetic fibers possess high strength without compromising safety requirements, for instance, aircraft and military applications, space applications, etc., whereas the use of synthetic fiber composites is unavoidable.

Synthetic–Synthetic

Ashraf *et al.* (2017) initially developed glass/kevlar fabrics (both woven and knitted) then fabricated epoxy based hybrid composites by hand lay-up technique; fiber volume fractions were controlled for 45%. Fourteen different types of stacking sequences were formulated to produce the hybrid composites (shown in Table 3). Results revealed that higher impact strength was achieved when increasing the knitted fabric percentage. But the tensile strength was found to be reduced when increasing the percentage of knitted fabric.

Increasing the kevlar fiber, on the other hand, led to an increase in impact strength. But, the tensile strength of hybrid composites was in contrast to the above, whereas the increase in knitted fabric resulted in a decrease in tensile strength. Since the knitted fabric was more crimping and interloping, the tensile strength was reduced.

In another study Bhudolia *et al.* (2018) used three different types of fibers such as E-glass (plain weave), Kevlar (twill weave), and thin carbon noncrimp fabric and fabricated epoxy based hybrid composites as shown in Fig. 4, using resin transfer molding technique.

Results revealed that increasing the high stiffness Kevlar fiber (GK₃C₄)_s resulted to produce higher flexural strength (458.76 MPa) and flexural modulus (31.56 GPa). The peak impact load of hybrid composites was determined by the total number of fabric layers. However, the increase in peak load with the increase in Kevlar fibers and the reduction of E-glass fibers was observed with the same number of fabric layers. Due to its ductile behavior, the absorbed energy was found to depend heavily on the number of glass layers. Severe fiber breakage with the increase of E-glass fibers and the reduction of Kevlar fibers was observed at the bottom of the specimen.

Mechanical Properties of Hybrid Bioresin Composites

Sustainable material systems have become inevitable due to the mounting concerns over environmental pollution. Greenhouse gas emissions, toxicity, and the depletion of petroleum resources are the major concerns of material scientists all over the world (Faruk *et al.*, 2012). In this context, the development of sustainable material systems requires the increased application of existing green materials. The existing class of materials possessing excellent environmental credentials are green composites, where biopolymers derived from bioresources are reinforced with natural fibers or fillers (Dicker *et al.*, 2014). There are several recently published research works based on green composites for different applications such as automotive (Koronis *et al.*, 2013; Oksman *et al.*, 2003), construction (Dittenber and GangaRao, 2012; Karbhari and Seible, 1999), packaging (Kumar *et al.*, 2018; Senthil Muthu Kumar *et al.*, 2018), biomedical (Sivaranjana *et al.*, 2017; Indiradevi *et al.*, 2018), etc. It is to be noted here that the aforesaid biopolymers may lack in certain characteristics like tensile and thermal properties. Hence, it becomes important to enhance the functional properties by reinforcement of fillers or fibers. Recently, natural fibers are gaining more use as reinforcement materials in biobased composites due to their wide availability, low cost, comparable strength with their synthetic counterparts, and more importantly their degradable nature. The natural fibers have relatively complicated structure with rigid cellulose surrounded by soft hemicelluloses and lignin. They are helically wound along the fiber axis, which makes them more stable and requires more load to break them (Rong *et al.*, 2001). This makes the natural fibers a favorable component in the

making of composites. Further, reinforcement of two or more fibers with the polymer matrix leads to the formation of hybrid composites. The main concept in hybrid composites is to bring the advantages of both the fibers to enhance the functional properties of the material for the targeted application. This section focuses mainly on the mechanical properties of hybrid composites with an emphasis on biobased polymers and natural fibers.

As already known, green hybrid composites are a combination of a biopolymer or resin derived from different biological resources and two or more natural fibers reinforced with the resin. There are many biopolymers that exist. And the commonly used biopolymers in composites are PLA, polyhydroxybutyrate, starch, cellulose, and so on. Similarly, there are many natural fibers such as kenaf, bamboo, flax, sisal, hemp, jute, etc. used as reinforcements in composite materials (Shogren *et al.*, 2004; Staiger and Tucker, 2008).

The properties of the composites are mostly influenced by the physical properties of both the matrix and the reinforcing fiber. The physical properties include fiber dimensions, strength, and structure. In this direction, many researchers have worked on the hybridization and studied the effect of hybridization on the mechanical properties (Aji *et al.*, 2013; Idicula *et al.*, 2010). Green hybrid composites were prepared using PLA as matrix and kenaf, bamboo, and coir fibers by Yusoff *et al.* (2016) They prepared three different stacking designs such as bamboo-coir/PLA, kenaf-coir/PLA, and kenaf-bamboo-coir/PLA with constant weight percentages of fiber to matrix and studied their mechanical properties. The kenaf-bamboo-coir/PLA hybrid composites possessed the highest tensile strength and modulus of 187 MPa and 7.5 GPa respectively. The lowest tensile strength of 105 MPa was exhibited by kenaf-coir/PLA hybrid composites, but it produced a tensile modulus of 7.3 GPa, which was slightly less than the kenaf-bamboo-coir/PLA hybrid composites. The toughness of the hybrid composites was found at 0.97 MJ/m³, 3.54 MJ/m³, and 4.45 MJ/m³ for kenaf-coir/PLA, bamboo-coir/PLA, and kenaf-bamboo-coir/PLA respectively. The higher toughness could be attributed to the optimum fraction of fiber in the composites (Nam *et al.*, 2011). The flexural strength of kenaf-bamboo-coir/PLA and bamboo-coir/PLA hybrids was higher than that of the kenaf-coir/PLA hybrid composites. This could be ascribed to the influence of the strong kenaf and bamboo outer layer in the hybrid composites. A strong interaction between the fiber cell wall and the matrix may result in enhanced flexural properties (Almeida *et al.*, 2013). So, they concluded that the bamboo and KFs compensated the lower strength of coir fiber by bearing the tensile load while the coir fiber contributed in the enhanced toughness of the hybrid green composites.

A study on the impact properties of basalt, flax, and green vinyl ester hybrid composites was reported by Živković *et al.* (2017). They tested the impact property of the hybrid composites in wet and dry conditions. They reported similar impact behavior of dry and wet hybrids with very small difference in the values. The values at different impact height of 2, 2.5, and 3 m were 11.01, 15.85, and 22.66 J respectively.

Huda *et al.* (2007) studied the mechanical properties of PLA based hybrid composites with recycled newspaper cellulose fibers (RCNF) and talc. They investigated the effect of varying concentrations of fillers with and without chemical treatment on the mechanical properties. The flexural and impact properties of the PLA/RCNF composites were enhanced with the addition of 10 wt% of silane treated talc. The flexural strength and modulus of the PLA/RCNF before hybridization was found to be 77 MPa and 6.7 GPa respectively, while the hybridized PLA/RCNF with 10 wt% silane treated talc produced 132 MPa and 15.3 GPa. Similarly, they also investigated the same having PP as the polymer matrix. A similar trend was also noticed when using PP/RCNF with 10 wt% of silane

treated talc. There was a 17% improvement in the impact properties of the PP hybrid composites compared with neat PP. The enhanced mechanical properties of PLA or PP hybrid composites were mainly due to the reinforcement of silane treated talc that enhanced the interaction at the polymer/talc interphase.

Another interesting study (Jacob *et al.*, 2004, 2006) investigated the mechanical and stress relaxation of rubber hybrid composites. Natural rubber was reinforced with sisal and oil palm fibers. The level interfacial adhesion between the matrix and the fibers was poor and when stress was applied it resulted in fiber pull-out from the rubber leaving gaping cavities. Hence, a chemical modification was done with 4% NaOH solution. They found that the mechanical properties increased and the rate of relaxation decreased with chemical modification.

Okubo *et al.* (2009) developed hybrid biocomposite with PLA reinforced with microfibrillated cellulose (MFC) and bamboo fiber. They found that the sudden crack growth was arrested due to the interphase between the cellulose and the PLA matrix around the bamboo fiber. This resulted in better tensile properties and further the diffusion of 1 wt% of MFC in PLA matrix drastically improved the strain energy of the bamboo/PLA composite up to 200%.

From these studies, it can be concluded that the mechanical properties of the hybrid composites can be enhanced by increasing the volume fraction of high strength fibers and chemical treatment of natural fibers can play a major role in the improvement of interfacial adhesion between the matrix and the fibers (Nunna *et al.*, 2012). Further, the exploration of biobased or natural fibers as reinforcing agents is found to be plenty compared with the exploration of biobased or natural polymer matrices in the fabrication of hybrid composites. Very few natural polymers are used as matrices in hybrid composites. Hence, the authors feel that there are scopes in the utilization of biopolymers in hybrid green composites, which can be a great innovation in terms of environmental aspects and enhanced properties.

Conclusion

This paper presents the different combinations of reinforcement used in the hybrid composites such as synthetic–natural, synthetic–synthetic, natural–natural and how these affect performance. Generally, the variation of hybrid composites is fabricated to improve the interfacial adhesion between the fiber and matrix of the composites. In this review, the interfacial properties were assessed through the experimental results and morphological analysis. Different types of fiber yield a variation of performance in the composites. Variation matrix systems have different properties that are very sensitive to processing methods such as fiber volume fraction, fiber length, and fiber orientation. Besides, the mechanical properties of hybrid composites not only depend the fabrication types, but also depend on the fiber modification. Fiber modification can enhance the interfacial adhesion between the matrix and fiber. Natural–synthetic can be combined to produce hybrid composite, which takes full advantage of the best properties of the constituents.

Introduction

Tetragonal tungsten bronze (TTB) ferroelectric oxide type compounds constitute one of largest and intensively studied crystalline families (Podlozhenov *et al.*, 2006; Allouche *et al.*, 2016; Castel *et al.*, 2009). The TTB structure is described as a framework of MO_6 (here $\text{M}=\text{Nb}$) octahedra sharing corners, which reveals in c-axis direction three kinds of tunnels with pentagonal (p), square (s) and triangular (t) section (Jamieson *et al.*, 1969; Ravez and Elouadi, 1975; Ikeuchi *et al.*, 2017). The first two sites with coordination numbers 15 and 12 respectively, can be occupied by ions of large size while the third one, with the coordination number 9, can only be occupied by small size ions (Ravez *et al.*, 1972b; Ma *et al.*, 2015). These compounds present a fundamental interest in technology due to their ferroelectric properties, electrical and optical properties. The physical properties (ferroelectric, pyroelectric, ferroelastic, piezoelectric, second harmonic generation and nonlinear optic) can be tuned and controlled through the chemical content in the cationic channels. (Ballman and Brown, 1967; Imai *et al.*, 1997; Neurgaonkar and Cory, 1986; Foulon *et al.*, 1996; Ahamad *et al.*, 2009) Thus, a large variety of phase transitions or diffuse ferroelectric transitions were reported in this family of compounds (El Alaoui Belghiti *et al.*, 2002; Ke *et al.*, 2008).

Their high electro-optic coefficients and strong photorefractive effects make the TTB oxides attractive for technological applications as holographic storages, spatial light modulators, pyroelectric detectors, surface acoustic wave (SAW) devices and beam steering (Imai *et al.*, 1997; Neurgaonkar *et al.*, 1984; Neurgaonkar *et al.*, 1986; Bian and Frejlich, 1995; Lin *et al.*, 2016; Liu *et al.*, 2007). TTB materials crystallize easily and are generally transparent in the visible light (Foulon *et al.*, 1996). They are widely used for nonlinear optics applications because of their stability under an intense laser irradiation (Wei *et al.*, 2014; Zhu *et al.*, 2013). Their large non-linear and piezoelectric coefficients make them excellent materials in electro-optics, optoelectronics and sensor physics (Gagou *et al.*, 2012; Bobbs *et al.*, 1985; Neurgaonkar and Wu, 1987; Adachi *et al.*, 2013; Sakamoto and Yazaki, 2003; Vazquez *et al.*, 1991). For instance, $\text{K}_3\text{Li}_2\text{Nb}_5\text{O}_{15}$ is used as frequency doubler diode between 790 and 920 nm to generate the second harmonic of a blue-violet laser at room temperature and photorefractive properties (Vazquez *et al.*, 1991; Foulon *et al.*, 1997; Kaigawa *et al.*, 2002; Zhang *et al.*, 1996). In some TTB compounds, the replacement of niobium by tantalum leads to a decreasing of the Curie temperature and relaxor-type ferroelectric behavior (Castel *et al.*, 2009; Lu *et al.*, 1993). The value of curie temperature in TTB compound is associated with the rigidity of the covalent links between the ions located within the oxygen octahedra (transition/alkali metal), the size and the electronic structure of cations in the tunnels and the filling of the triangular sites implying their use in electrochemical applications (Castel *et al.*, 2009; Ma *et al.*, 2015; Han *et al.*, 2016). The structure stability mainly depends on steric parameter (Ravez *et al.*, 1972b; Parida *et al.*, 2013; Hornebecq *et al.*, 2001) and the direction of the spontaneous polarization can be altered depending on the nature of the atom that occupies the tunnels (Ravez *et al.*, 1972a; Pouchard *et al.*, 1975).

The lead-containing TTB compounds generally exhibit a ferroelectric orthorhombic phase with a distortion due to the strong polarizability of Pb^{2+} ions which causes a structural anisotropy (Hornebecq *et al.*, 2001, 1998). The well-known compounds are derived from PbNb_2O_6 which exhibits ferroelectric properties (Ravez and Elouadi, 1975; Labbé *et al.*, 1977). The distortions of the octahedra lead to a shift of the cation from its center and contribute to the increase of the curie temperature (T_C). Above T_C , the thermal agitation is sufficient to allow atom motions in all the directions cancelling the polarization (Vazquez *et al.*, 1991).

Ravez *et al.* (1972a) have studied TTB niobates including the three compounds $\text{BaCaNaNb}_5\text{O}_{15}$, $\text{SrCaKNb}_5\text{O}_{15}$ and $\text{BaCaKNb}_5\text{O}_{15}$ which showed the influence of cationic occupancy. They showed that the Curie temperature increases with the ionic radius of the cations inserted in the (p) and (s) sites. These authors proved that no ion in TTB structure staying in the (t) cavities can occupy the larger sites (p) and (s) and conversely, any cation occupying the sites (p) and (s) can occupy (t) sites. This distinguishes the TTB from perovskite compounds and can be attributed to the greater stability of the perovskite structure

and the anisotropy of the crystal lattice of TTB compounds (Chen *et al.*, 2003). This behavior is supported by the work of Pouchard *et al.* (1975) which evidenced the great decrease of the covalent metal-oxygen bonds occurring when niobium was substituted by tantalum.

Previous study was focussed on compounds of rare earth family $\text{Pb}_{1.6}\text{K}_{1.2}\text{R}_{0.2}\text{Nb}_5\text{O}_{15}$ (PKRN) (Oualla *et al.*, 2003) with various chemical elements, (R=La, Nd, Sm, Eu and Gd) of TTB-type ferroelectrics that were synthesized by solid state reaction and characterized by powder x-ray and dielectric measurements. The transition temperature PKRN was shown to decrease slowly with increasing of the rare earth ion (R) radius (Oualla *et al.*, 2003). Furthermore, room temperature x-ray powder diffraction patterns had been recorded on several compositions (from $x=0.0$ to $x=1.0$) in $\text{Pb}_{2(1-x)}\text{Gd}_x\text{K}_{1+x}\text{Nb}_5\text{O}_{15}$ family and structural analysis versus Gd-content had been performed based on Rietveld method (Rodríguez-Carvajal, 1993). Some of the results of this study were also reported (Gagou *et al.*, 2007; Amira *et al.*, 2010) that showed the existence of three regions versus Gd-content which merits complementary analysis.

Transition lines appeared from orthorhombic symmetry $Cm2m$ (No. 38) in Region I, to another orthorhombic symmetry $Pba2$ (No. 32) in Region-II, that occurred at $x \sim 0.3$ whereas the compounds in Region III ($x > 0.7$) present a tetragonal structure with $P4bm$ (No. 100) symmetry (Amira *et al.*, 2010). These observations are in favor of the tilting of the polarization from 0° (for $x=0$) to 90° (for $x=1$), which means that the polarization tilts from (a, b)-plane in Region I and goes to the c-axis direction when Gd-content increases. However, in Region II, the x-ray diffraction patterns present a series of Bragg peaks which can be indexed in tetragonal or orthorhombic symmetries. In this region, any better results were obtained without assuming a combination of coexistence of two symmetries ($Pab2$ and $P4bm$). Thereafter, when x increases from $x=0.3$ to $x=0.7$ there is a decreasing of the symmetries proportion of $Pab2$, comparatively to $P4bm$ in a coherent way; that allows us to build the intermediate phase. Beyond this range of compositions, pure symmetries were found.

In region II, the material appears to be a mixture of both phases, similar to what was found in numerous ferroelectric compounds (Cao *et al.*, 2010a,b; Shrout, 2002). These two ferroelectric phases are separated by the so-called morphotropic phase boundary (MPB) (Shrout, 2002; Elkechai *et al.*, 1996; Rao and Wang, 2007) which would take place at room temperature around $x=0.45$. If the situation is analogous to what happens in the perovskite family as mentioned by Frantti *et al.* (2009) the mixture of both phases could lead to enhance piezoelectric properties. Because of the steepness of the phase boundary, any small composition inhomogeneity leads to a coexistence state in this region.

Nowadays, in order to miniaturize the physical devices, and with the development of various physical deposition techniques, this family of compounds can be deposited as thin films and as super lattices by pulsed laser deposition (PLD) as it was reported previously by Allouche *et al.* (2016) and Gagou *et al.* (2012). This work follows the earlier work that was published previously (Gagou *et al.*, 2007). Raman spectroscopy study of $\text{Pb}_{2(1-x)}\text{Gd}_x\text{K}_{1+x}\text{Nb}_5\text{O}_{15}$ (PGKN) has been reported on the structural properties of this family that revealed a more ordered structure when Gd-content increases (Amira *et al.*, 2010).

In the present work, we perform a global analysis on the complete T-x phase diagram of this solid solution, by determining the variation of structural symmetry depending on the temperature, for given compositions. The nature of the intermediate phase between rich and low Gd-content compounds at room temperature is also investigated that permits to elucidate the nature of intermediate phase observed during structural changes versus temperature in the composition of $x=1$ as reported recently (Gagou *et al.*, 2014). The influence of the variation of Gd rate from $x=0$ ($\text{Pb}_2\text{KNb}_5\text{O}_{15}$) to $x=1$ (lead free compound $\text{K}_2\text{GdNb}_5\text{O}_{15}$) is studied by means of dielectric measurements, scanning electron microscopy (SEM), differential scanning calorimetry (DSC) and powder x-ray diffraction versus temperature, for the compositions of $x=0.1$, $x=0.4$ and $x=0.9$ which correspond to each region of the determined phase diagram.

The aim this work is to investigate the influence of Gd^{3+} ions occupancy in the (s) and (p) channels, on the TTB structural properties of the present solid solution. Main focused was done on the structural changes at room temperature varying the gadolinium content and then, we highlight the structural changes in all compositions over temperature, based on dielectric measurements.

Experimental

PGKN compounds were prepared by solid state reaction, with three different oxides such as PbO , Gd_2O_3 and Nb_2O_5 and potassium carbonate K_2CO_3 of 99.99% purity from Sigma-Aldrich. The finely crushed mixtures were pre-heated at 650°C during 6 h, and then annealed at 1200°C during 12 h. Each thermal treatment was followed by crushing in order to obtain well homogenized mixtures. Powders were then compacted under a pressure of 200 MPa, to obtain cylindrical pellets with 13 mm diameter and 1 mm thickness. These pellets were sintered during 2 h at 1270°C . The obtained ceramics had a compactness of about 97% considering theoretical versus experimental calculations. All the ceramics were elaborated in the same conditions. Powder x-ray measurements were performed using a Bruker AXES-D8 Advanced Diffractometer with a Cobalt radiation $\lambda_{\text{CoK}\alpha 1} = 1.7889 \text{ \AA}$ and $\lambda_{\text{CoK}\alpha 2} = 1.7928 \text{ \AA}$. A cylindrical furnace allowed collecting x-ray patterns in Debye-Scherrer geometry versus temperature. Scanning electron microscopy measurements were performed using a JEOL JSM-5500 microscope in order to characterize the micro-structure of the samples. DSC measurements were performed using NETZSCH DSC 204 F1 apparatus under argon gas flow. Dielectric measurements were carried out using a Solartron SI-1260 spectrometer in the 10^1 – 10^6 Hz frequency range. Electrodes were deposited by platinum sputtering on the two faces of the ceramic pellets to get capacitor shaped samples. An alternative voltage source of 1 V maximal amplitude was applied on the 0.8 mm thickness samples and the temperature was controlled using a Linkam TS 93 hot stage allowing $\pm 0.1^\circ\text{C}$ temperature stability.

Results and Discussions

Dielectric Measurements

Figs. 1–3 show the variation of real part of dielectric permittivity versus temperature on heating and cooling, for three representative compositions in this family such as $x=0.0$, $x=0.5$ and $x=0.9$. Thermal hysteresis behavior of each real part of permittivity at the measuring frequency of 100 kHz were shown in Figs. 1(a), 2(a) and 3(a) and their frequency dependence are shown in the Figs. 1(b), 2(b) and 3(b), respectively. Higher dielectric dispersion as a function of frequency was observed for weak Gd-content compounds such as for $x=0.0$ (Fig. 1(b)). This dielectric dispersion attenuates progressively toward intermediate Gd-content compounds (Fig. 2(b)) and becomes very weak for the rich Gd-content compounds (Fig. 3(b)). This behavior was attributed to atomic reordering in this system with the gadolinium rate.

It was observed in Fig. 4 that a significant variation of the dielectric anomaly shapes from one region to another. The width of the dielectric permittivity thermal hysteresis increases with Gd-content followed with a slight decrease in rich Gd-content part. This behavior is in favor of a structural change from a second order (without any drastic permittivity jump and small thermal hysteresis) to a first order (with abrupt permittivity jump and large thermal hysteresis) type transition, when Gd-content increases, as observed in Figs. 1(a), 2(a) and 3(a), respectively. We can clearly observe in Fig. 4(c), in the Gd-rich compounds ($x \geq 0.7$), the

Fig. 1 Dielectric constant versus temperature for (a) $x=0.0$ at 100 kHz on heating and cooling, and (b) evolution of the maximum at several frequencies on heating.

Fig. 2 Dielectric constant versus temperature for (a) $x=0.5$ at 100 kHz on heating and cooling, and (b) evolution of the maximum at several frequencies on heating.

Fig. 3 Dielectric constant versus temperature for (a) $x=0.9$ at 100 kHz on heating and cooling and (b) evolution of the maximum at several frequencies on heating.

Fig. 4 Dielectric permittivity at $f=10\text{ kHz}$ as a function of temperature on heating, for different compositions: (a) $x=0$ to $x=0.2$ (region I), (b) $x=0.3$ to $x=0.6$ (region II), (c) $x=0.7$ to $x=1$ (region III).

presence of a second anomaly (at T_b) indicating two phase transitions observable on the curve of dielectric permittivity versus temperature. However, only one dielectric anomaly was evidenced for the other compositions (lower Gd-content, with $x < 0.7$). Furthermore, the temperature of the maximum of real permittivity does not present any change with the frequency in the range of 10 Hz to 1 MHz, which indicates the absence of any relaxor behavior in this solid solution. Dielectric measurements show also a decrease of the permittivity maximum value when the Gd-content increases as shown in Fig. 4.

For example, the permittivity value that was about 3400 at $T_C=425^{\circ}\text{C}$ for $x=0.0$ (Fig. 4(a)), decreases to about 1650 for $x=0.3$ at $T_C=204^{\circ}\text{C}$ (Fig. 4(b)) and to about 380 for $x=0.7$ observed at $T_C=230^{\circ}\text{C}$. This is attributed to the decreasing of lead content when the Gd-content x increases. It can be concluded that the high polarizability of Pb^{2+} ion is responsible for the strong ferroelectric behavior in this system, as reported previously by Sciau *et al.* (1993) and Taifi *et al.* (2010).

In Region I (Fig. 1(a)), the curves of real permittivity ($\epsilon_r(T)$) present a thermal hysteresis of about 10°C in the low temperature phase. They are also characterized by a rapid decrease of $T_C(x)$ as shown in Fig. 4(a). The absence of visible jump indicates a

diffuse character of the structural change and a second order type transition when crossing the T_C line in this region. The frequency dispersion behavior (decreasing of the peak magnitude when the frequency increases) that was observed also in Fig. 1(b), Fig. 2(b) and Fig. 3(b) is typical for ceramics and attributed to grain boundaries and grain size effects.

In region II, the behavior is quite different. The curves of $\varepsilon_r(T)$ still present λ -shaped but with a broader peak at T_C and a wider thermal hysteresis (of about 70°C) (see Fig. 2(a)), whereas the frequency dispersion weakens with frequency and $T_C(x)$ is slightly increases, as shown in Fig. 2(b). Such a behavior where an excess of dielectric constant occurs in the region below the dielectric permittivity peak, recalls the situation that happens in potassium dihydrogen phosphate KH_2PO_4 (KDP) that was shown to be dependent on defect concentration (Petrova and Stishov, 2013; Eberhard and Horn, 1975; Sidorkin, 2006) or related to the anisotropy in $\text{K}_{0.4}\text{Li}_{0.6}\text{NbO}_3$ (KLN) (Uitert *et al.*, 1967). In PGKN, this effect could be attributed to the interaction between ferroelectric domain walls and defects. The analogy of these behavior between irradiated KDP and PGKN materials belonging to region II, suggests that a particular situation occurs in this region, with respect to the wall-defect interaction, for instance around 100–150°C for $x=0.5$ (see Fig. 2(a)).

In Region III, the permittivity jump corresponds to a clear first order type transition with larger thermal hysteresis of about 65°C as presented in Fig. 3(a) for the case of the composition $x=0.9$. This first anomaly is followed by a second one T_b above T_C that indicates a second phase change where an hysteresis is observed in a temperature range of about 10°C, observable in Figs. 3(a) and 4(c). This second anomaly occurs without clear permittivity jump, and seems to exhibit a second order type transition character.

Moreover, from the analysis of thermal dielectric permittivity behavior $\varepsilon_r(T)$, we deduced that the temperature corresponding to the real permittivity maxima decreases rapidly in Region I, then increases smoothly in Region II and then increases normally in Region III where we observe a second anomaly that increases rapidly with Gd-content. The temperatures of the second anomalies are denoted T_b in Fig. 4(c).

DSC Measurements

At the same temperature corresponding to dielectric anomalies, DSC measurements show anomalous behavior too. Calorimetric analysis shows some excess of specific heats in this system, in appropriate temperature ranges. DSC measurement results were summarized into three curves corresponding to $x=0.0$, 0.5 and 0.9 and plotted in Fig. 5, where we observe the specific heat flow excess (DSC signal) versus temperature in the three different regions. The composition $x=0.0$ correspond to Region I, $x=0.5$ to Region II and $x=0.9$ to Region III. All curves show corrected values of DSC signal excess, after subtraction of baseline, following a classic procedure.

For the composition $x=0.0$ (Fig. 5(a)) it is clearly observed a broader excess of specific heat around the temperature of the dielectric anomaly ($T_C=425^\circ\text{C}$), that is in favor of a second order type transition highlighted previously by dielectric measurement. The curve corresponding to $x=0.5$ (Fig. 5(b)) shows a λ -shape and symmetrical anomaly at $T_C=216^\circ\text{C}$, in favor of a second order character of the transition. This composition, which corresponds to the coexistence of two phases, presents the weakest excess of specific heat and is in accordance with the temperature position of dielectric permittivity anomaly. However, the curve that corresponds to $x=0.9$ (Fig. 5(c)) shows a full first order type transition exhibited by the clear jump of the DSC signal with the highest excess of specific heat and a typical asymmetry of the peak at the first anomaly, observed at $T_C=226^\circ\text{C}$. This behavior is characteristic of the Region III. As in dielectric response, this anomaly is followed by a second anomaly characterized by a broad signal approximately centered on $T_b=360^\circ\text{C}$ as observed from dielectric measurement. All these observations are in accordance with results obtained in dielectric measurements.

XRD and Raman Spectroscopy Studies

X-ray patterns of the representative compositions of $x=0.1$, $x=0.4$ and $x=0.9$ were recorded as a function of temperature (in the temperature range of 30–600°C). The temperature dependence of lattice parameters a , b and c for each composition are presented in Fig. 6(a–c) respectively. For $x=0.1$ the splitting of a and b lattice parameters in ferroelectric phase shown in Fig. 6(a), occurs at a temperature that coincides with the ferroelectric transition temperature deduced from the dielectric data. This indicates that the structural change occurs between the ferroelectric (orthorhombic) $\text{Cm}2m$ (No. 38) phase at low temperature to the paraelectric, high symmetry tetragonal $P4/mbm$ (No. 127) phase, without evidence of an intermediate phase. For $x=0.4$, in the low temperature phase when $T<60^\circ\text{C}$ the structure is well described by the $Pba2$ (No. 32) space group. We performed also x-ray refinement between 60°C and 120°C. The structure can be refined in the $Pba2$ symmetry as well as in $P4bm$ symmetry. The ferroelectric transition evidenced by the dielectric anomaly is found at the same temperature (see Fig. 4(b)), where ferroelastic splitting at cooling occurred between $P4/mbm$ and $P4bm$ space groups as reported on Fig. 6(b). For the compound with $x=0.90$, all the phases are found to be tetragonal but compatible with different symmetry groups. In the intermediate temperature region ($230^\circ\text{C}<T<360^\circ\text{C}$) this compound exhibits the symmetry group $P4/mbm$ with a doubling of TTB parent unit cell volume, with lattice parameters $a\sqrt{2}$, $a\sqrt{2}$ and c , or in another possible space group $P4nc$ (No. 104) with doubling of c -axis parameter that is also a subgroup of the high symmetry space group ($P4/mbm$).

These behaviors were reported very recently on the compound $\text{GdK}_2\text{Nb}_5\text{O}_{15}$ (with $x=1.0$) (Gagou *et al.*, 2014) where this doubling of c -axis lattice parameter was attributed to an antiferroelectric ordering. At higher temperature ($T>T_b$) the tetragonal structure is stabilized in $P4/mbm$ space group as for all TTB materials. The variation of the lattice parameters versus

Fig. 5 DSC Signal versus temperature on heating for the three compositions (a) $x=0.0$, (b) $x=0.5$ and (c) $x=0.9$, each Gd-content belonging to Region I, II and III respectively. The DSC signals were corrected by subtracting background obtained by polynomial interpolation and the values correspond to excess of specific heat.

temperature is featured in the Fig. 6(c) as characteristic of compounds in region-III. The $a=b$ parameter increases and the main anomaly was observed on the c parameter at about 230 °C (Fig. 6(c)). The phase transitions between the high temperature tetragonal structure and the low temperature can be described by the loss of the mirror m_z (perpendicular to c -axis) symmetry and the doubling of the c lattice parameter with apparition of the polar axis in $P4bm$ symmetry, when the temperature is lowered.

Fig. 7(a) and (b) show respectively typical x-ray patterns and Raman spectra of the compositions ($x=0$, 0.5 and 0.9), each composition corresponds to Region I, II and III, respectively. The x-axis of these plots are restricted for better understand. The space groups assignment were consistent with, for example, the symmetry change of the indexed line (320) in (tetragonal, Region III) to (321) in (tetragonal, Region II) and its splitting to (510) + (150) in (orthorhombic, Region I), that provide the distortions in (a,b) plane for low Gd-content compounds (rich Pb-content compound), since all the (00ℓ) lines remained unchanged as it can be seen in Fig. 7(a). These analysis were applicable for the indexed line (620) that disappeared in intermediate region before splitting into (840) + (480) in Region I. These results, related to symmetry assignments, were also supported by Raman modes changes with Gd-content in this system, as shown in Fig. 7(b), where a disordered was observed structure from less Gd-content compounds to more and more ordered structure when Gd-content increases.

Relation Between Microstructure and Properties

For better understand of the structural changes and ferroelectric behavior deduced from dielectric measurements it is worth to analyse microstructure effect in this system. For instance, the width of the coexistence region has been connected to the particle size as reported by Mittemeijer and Welzel (2008) and depends on the processing conditions. A spatial variation of composition could also induce some phenomena that were observed, like the wide hysteresis and the diffuse nature of the transitions. To check these points, SEM images have been recorded and shown in Fig. 8. The three compounds: $x=0.1$ (Fig. 8(a)), $x=0.4$ (Fig. 8(b)) and $x=0.9$ (Fig. 8(c)) present typical grain sizes in each image belonging to their related region versus composition. They show a good

Fig. 6 Unit cell parameters versus temperature for compound with (a) $x=0.1$, (b) $x=0.4$ and (c) $x=0.9$.

crystallization in agreement with the powder x-ray diffraction results which showed narrow lines x-ray patterns, as indicated in Amira *et al.* (2010).

The grain size and the strain analysis of the pseudo-voigt peak shape profile were performed at room temperature using Debye-Scherrer Formula (Welzel and Mittemeijer, 2005). The results of grain size and strain analysis were presented in Figs. 9 and 10, respectively. We can observe the rapid decreasing of the apparent crystallite size with the Gd-content x , followed by a slight decreasing attempting a minimum value in the phases coexistence region II ($0.4 < x < 0.7$).

In the single phase region III ($x > 0.7$), the apparent crystallite size decreases with Gd-content, from micron to sub-micron size (refer to Fig. 8) leading to a more compact ferroelectric compound. Simultaneously, the strain analysis (Fig. 9) indicates a constant and a weak strain (0.2%) up to the composition $x < 0.4$. In the coexistence region ($0.3 < x < 0.7$) the strain increases rapidly for both symmetries and then decreases rapidly with Gd-content to negative values that induce lattice expansion for $x=0.7$. Moreover, for the composition $x > 0.7$ in the $P4bm$ single phase, the mean strain level increases to attempt a level characteristic of the $Pba2$ single phase.

In a nutshell, in this crystalline phase, compounds with $P4bm$ symmetry phase are more plastic and lead to good density ceramics than those in $Pba2$ symmetry phase. This induce high stability and cohesion of chemical elements, since higher strain and mean crystallite-size are more reachable in the $P4bm$ phase ($x > 0.7$) than in the $Pba2$ phase ($x < 0.4$). All these phenomena are obviously connected to the Gd-content in this family, and Gd-rich compounds present the smallest grains. In this system the grain size decreases from about 5 μm (for $x=0.1$) to less than 1 μm for the compound with $x=0.9$.

Fig. 7 (a) X-ray patterns of the three composition ($x=0, 0.5$ and 0.9) highlighting structural phase changes in PGKN through the three regions. (b) The symmetry changes were confirmed by Raman spectra recorded on the three compositions.

Fig. 8 SEM images showing grain size morphology on ceramics of the three compositions; (a) $x=0.1$, (b) $x=0.4$ and (c) $x=0.9$ selected to be investigated.

Fig. 9 Evolution of the crystallite size as a function of Gd-content, deduced from powder x-ray diffraction data. (Red diamond symbol corresponds to $P4bm$ symmetry and black solid circle correspond to $Pba2$ symmetry).

Furthermore, compounds with the smaller grains have the sharper jump in the dielectric curves exhibiting a first order type phase transition with the larger dielectric anomalies. The smaller thermal hysteresis were obtained for the compositions having the larger grain sizes (for example, $x=0.1$) in a coherent way.

Fig. 10 Evolution of the mean strain as a function of Gd-content, deduced from powder X-ray diffraction data. (Red diamond symbol corresponds to *P4bm* symmetry and black solid circle correspond to *Pba2* symmetry).

Development of Phase Diagram

The data presented above can be summarized in a composition–temperature phase diagram (see Fig. 11), considered as a complete phase diagram in PGKN system, when compared to the previous version proposed in Amira *et al.* (2010). All the temperatures such as T_C and T_b highlighted in the previous analysis, were plotted as a function of the Gd-content in the whole composition, that permits us to build the (x, T) -phase diagram of this family. The results are summarized in Fig. 11 that proposes for the first time the temperature-composition phase diagram, which exhibits interesting phase transition lines and multiple points in this system. The first order transition character for Gd-rich compounds is connected with our previous reported Raman spectroscopy results on this family compound (Amira *et al.*, 2010), while the more ordered structure is observed in this region (Region-III) comparatively to disordered structure in compounds with low Gd content.

In Region I of this phase diagram ($x < 0.3$) the low temperature phase crystallizes in *Cm2m* symmetry group which means the polarization is oriented along the $(010)_o$ orthorhombic 2-fold axis which is perpendicular to the tetragonal $(001)_t$ direction. Ferroelectric properties of both structures are therefore clearly different.

This behavior permits us to conclude that PGKN family compounds exhibit an intermediate region ($0.3 < x < 0.7$) in the composition-temperature phase diagram between low Gd-content compounds (having orthorhombic ferroelectric phase with (a,b) -oriented polarization) and the rich Gd-content compounds (having tetragonal ferroelectric phase like in $\text{Ba}_2\text{NaNb}_5\text{O}_{15}$, with c -axis oriented polarization). In this phase (Region-II), the ferroelectric orthorhombic phase is induced by the ferroelastic distortion in (a,b) -plane and the polarization is related to the niobium atom displacement out of the equatorial plane position inside oxygen octahedra. Such a situation is typical for the traditional lead-containing TTB ferroelectrics like in $\text{Pb}_2\text{KNb}_5\text{O}_{15}$ and $\text{Pb}_{2.05}\text{Na}_{0.90}\text{Nb}_5\text{O}_{15}$ and some perovskite (Ravez and Elouadi, 1975; Sciau *et al.*, 1993; Glazer, 1972).

The symmetry group of this phase, *Pba2*, reveals moreover a spontaneous orthorhombic deformation that can be provided by the specific interaction of ferroelectric and ferroelastic coupling and atom motion through the tunnels along c -axis. Such a situation was observed previously in the TTB-type ferroelectric compound $\text{PbK}_2\text{LiNb}_5\text{O}_{15}$ (Gagou *et al.*, 2004). In *Pba2*, the polarization is oriented along the orthorhombic $(00\ell)_o$ axis, which coincides with the tetragonal $(00\ell)_t$ axis. This structural result is important because it is not possible to pass continuously from the structure with *Cm2m* to that with *Pba2* since the ferroelectric polarization changes its direction from $(110)_o$ to $(001)_t$ (with reference to tetragonal axes).

As a consequence, there should occur a first order transition line between both phases that could terminate in another multiple point in the phase diagram (denoted P_2 in Fig. 11), from which the morphotropic region could start on the right (Region-II). Inhomogeneities in the sample due to the morphotropic region may be at the origin of the special situation regarding interaction between domain walls and defects that was evoked above. In that region, the grain boundaries are expected to be more numerous and their role in the pinning of domain walls may be invoked as the determinant mechanism of domain walls-defects interaction to explain both the excess of dielectric constant on cooling, and the global thermal hysteresis. We expect that the special concentration ($x \sim 0.25$) where the polarization upsets into the basal plane, is a point of special interest in the neighborhood of which the instability of polarization orientation could have interesting physical properties. Moreover, due to the existence of the antiferroelectric symmetry the compositions in this region constitute potential candidates for electrostatic energy storage. PGKN system exhibits the presence of many rich phases symmetries whose determination requires complementary refinements and accurate studies, in particular taking into account the theoretical results of the analysis of rigid unit modes (RUMs) (Smirnov and Saint-Grégoire, 2014) in this crystalline family.

Fig. 11 Composition–Temperature phase diagram of PGKN compounds. Three regions may be distinguished (see text): region I in which phase transition occurs apparently between $P4/mbm$ and $Cm2m$ symmetries. The existence of an intermediate phase cannot be excluded from the data so that a triple point P_1 as shown close to $x=0$ compositions could be present. Region II is characterized by a coexistence zone (dashed region) between $P4bm$ and $Pba2$. There exists then a line between $Cm2m$ and $Pba2$ phases that ends at a multiple point P_2 . Finally, in region III phase transitions occur between tetragonal phases. In that region both transition lines seem to converge to a triple point P_3 that would lie around $x=0.5$ and $T=200^\circ\text{C}$.

Conclusion

TTB compounds containing gadolinium with the general formula $\text{Pb}_{2(1-x)}\text{Gd}_x\text{K}_{1+x}\text{Nb}_5\text{O}_{15}$ (PGKN) have been elaborated by solid state reaction, and have been studied to elucidate their structural electrical and calorimetric behaviors. A new composition–temperature phase diagram was established that appears to be very rich. The results are consistent with the presence of multiple points involving lines between paraelastic–paraelectric–ferroelastic–ferroelectric. Scanning Electron Microscopy shows various morphologies connected with Gd concentration and ferroelectric behaviors connected to grain size and strain analysis. At high temperature, all the compositions are compatible with $P4/mbm$ space group symmetry. At low temperature, three composition regions have been observed in the phase diagram: (i) compounds with a low Gd-content ($0 < x < 0.3$) are compatible with the $Cm2m$ space group, (ii) compounds with a rich Gd-content were refined in the $P4bm$ space group ($0.7 < x < 1$), (iii) compounds with intermediate Gd-content ($0.3 < x < 0.7$) show up a MPB as found in the perovskite family, that can be described as the coexistence of phases with space groups $Pba2$ and $P4bm$. This intermediate phase, that ranges in $0.3 < x < 0.7$, represents a domain where we could expect potential candidates for electrostatic energy storage materials.

Conversion of Renewable and Food Wastes Into Useful Products With Environmental Perspectives

Mohammad R Kasaai, Sari Agricultural Sciences and Natural Resources University, Sari, Mazandaran, Iran

© 2020 Elsevier Inc. All rights reserved.

Introduction

A variety of wastes are generated both in the land (forestry, agriculture, food and beverage) and marine sectors (Hettenhaus, 2011; Liu *et al.*, 1997; Pfaffin and Ziegler, 1998; Schiefelbein *et al.*, 1980; Van Luyen and Houn, 1996). Their accumulation on this planet (land and marine) results in several environmental difficulties, health issues, safety hazards, and prevent sustainable development in terms of resource recovery and recycling of waste materials (Taherzadeh and Karimi, 2008). Converting different wastes into value-added (food, feeds, fertilizer and others) products is an effective pathway to reduce environmental harms, and improve economic sustainability of wastes processing. Isolation of natural compounds from wastes generated in the various sectors or their conversion into useful compounds such as food ingredients, bio-fuel, and other value added products by respecting environmental demands is an interesting subjects (Taherzadeh and Karimi, 2008). This recycling approach brings benefits not only to the environments, but also to industries from economical point of view.

A review report for the conversion of different wastes generated from land (food, agriculture, and forestry) and marine sectors, into useful products, provides as a collection and a ready scientific report for investigators, who are involved in both research laboratories and industries. The objectives of this study were: (i) To provide a global information on the wastes generated from different (forestry, agriculture, food, beverage, and marine) sources; (ii) to convert several wastes with the renewable resources into by-products; (iii) to determine the required appropriate (s) conversion into useful components, considering environmental concerns, a gas emission, and a global warming; and (iv) to extract useful components from by-products for different applications.

General Aspects of Renewable and Food Wastes

Land and Marine Renewable Resources Wastes

A large amount of the renewable wastes have been accumulated in the nature (Hettenhaus, 2011; Liu *et al.*, 1997; Pfaffin and Ziegler, 1998; Schiefelbein *et al.*, 1980; Van Luyen and Houn, 1996). Leaves, stems, and stalks are major components of forestry residues (Mishra and Thakur, 2015). Agricultural wastes include leaves, stems, husks (the dry outer covering of various fruits or seeds), woody crops and stalks from different sources such as, corn fiber, corn stover, straw, hulls, peels and hells from cereals (corn, wheat, barely, rice, and sorghum), sugarcane bagasse, and brewer's spent grains (Hettenhaus, 2011; Liu *et al.*, 1997; Mishra and Thakur, 2015; Pfaffin and Ziegler, 1998; Schiefelbein *et al.*, 1980). Crop residues are the main part of agricultural biomass. Corn stover from crop residues and straws (Hettenhaus, 2011; Nelson *et al.*, 2011) from cereal grains (wheat, rice, oat, rye, and barley) are quantitatively the major parts of the residues. Maiorella (1985) reported that "1 kg grains as the main product" was obtained from the original harvested crops. The remained residues "which is straws and can be considered as a by-product" equal to 1–1.5 kg. Industrial processes and residues of agriculture resulted in different wastes including coconut biomass, citrus peels, sawdust, paper pulp, and paper mill sludge (Sadhu *et al.*, 2013). Citrus peel, cooking oil and cashew shell nut liquid were also used as wastes in different countries "China, Morocco, and European (UK, Spain, Greece)" (Lin *et al.*, 2013). Most of marine wastes obtained from crustacean shells (Van Luyen and Houn, 1996). Different wastes obtained from renewable resources were shown in Fig. 1.

Agricultural wastes include high amount of polysaccharides (cellulose, hemicellulose), lignin, and inorganic materials (Ragauskas *et al.*, 2014). Various ingredients of biomass are cellulose, lignin, hemicellulose, proteins, fats and minerals (Sinag *et al.*, 2010). Ligno-cellulose is a complex material comprising two polysaccharides (cellulose and hemicellulose), and a phenolic polymer, lignin, as the major structural component (Howard *et al.*, 2011). They may be combined with small amounts of other components like acetyl groups, minerals and phenolic substituents (Isikgor and Becer, 2015). There are multiple sources of lingo-cellulosic wastes from agriculture and forest residues and industrial agricultural processes (citrus peel, coconut biomass, sawdust, paper pulp, and paper mill sludge) (Hettenhaus, 2011; Liu *et al.*, 1997; Pfaffin and Ziegler, 1998; Sadhu *et al.*, 2013; Schiefelbein *et al.*, 1980). Ligno-cellulosic biomass is a major component of plants (stalks, leaves and roots). Depending on the type of lignocellulosic biomass, these polymers are organized into complex non-uniform three-dimensional structures to different degrees and varying relative compositions. These polymers are closely associated with each other. Basically, cellulose forms a skeleton, which is surrounded by hemicellulose and lignin (Mishra and Thakur, 2015). Lignocellulose has evolved to resist degradation. This is due to the crystallinity of cellulose, hydrophobicity of lignin, and encapsulation of cellulose by the lignin–hemicellulose matrix (Agbor *et al.*, 2011; Barakat *et al.*, 2013). Although the composition of agricultural crop wastes is different, the typical percentages of the dominant chemical composition in corn stover, rice straw, and wheat straw are 35%–50% cellulose, 20%–35% hemicellulose, and 5%–25% lignin (Binod *et al.*, 2010; Lomborg *et al.*, 2010; Weiss *et al.*, 2010). In general, lignocellulosic

Fig. 1 Major substances derived from land and marine renewable resources.

biomass composed mainly of two carbohydrate polymers cellulose (30%–60%) and hemicelluloses (20%–40%) and an aromatic polymer lignin (10%–25%), which are interlinked to each other in a hetero-matrix. Approximately 90% of dry matter in lignocellulosics consists of cellulose, hemicelluloses and lignin, whereas the rest comprises of ash and extractives (Isikgor and Becer, 2015; Nanda *et al.*, 2014, 2012). The carbohydrate polymers contain different sugar monomers (six and five carbon sugars) and they are tightly bound to lignin. The lingo-cellulosic biomass is abundant, renewable resources on the earth and obtained from forest and agriculture residues (Akhtar *et al.*, 2015; Mishra and Thakur, 2015; Mosier *et al.*, 2005). In the cell wall, cellulose acts as the structural framework, and hemicellulose retains the water for the lingo-cellulosic (lingo-cellulosic) biomass. Lignin plays a role as an adhesive between the various cell wall components. Lignin is also an important component for mechanical support, water transport, and defense against natural invasion (Ragauskas *et al.*, 2014). Cellulose, “the most abundant biopolymer on the earth” is a linear polymer of glucose with β -1, 4-linkages. However, it has crystalline structure and is highly resistant to hydrolysis by both enzymatic and chemical means. Cellulose in secondary cell walls is embedded in a matrix of hemicellulose and lignin with lower amounts of pectin and protein.

Food Wastes

Wastes produced from food industries include: “Dairy products (dilutions of whole milk, separated milk, butter milk, whey, sour milk); brewed and distilled beverages (steeping and pressing of grains; residues from distillation of alcohol, condensate from stillage evaporation); meat and poultry products (stockyards, slaughtering of animals, rendering of bones and fats, residues in condensates, grease and wash water, picking chickens); beet sugars (juicing waters, draining from lime sludge, condensates after evaporator, juice and extracted sugars); cane sugar (spillage from extraction, clarification, evaporation, cooling, and condenser waters); wastes with a high water content such as garbage; and carbohydrate-based (starch, corn, potatoes, and wheat) materials” (Liu *et al.*, 1997; Pfaffin and Ziegler, 1998). Food wastes are sustainable raw materials to produce high value-added products (Lin *et al.*, 2013). Processing of fruits and vegetables (fennels, carrots, citrus, tomatoes) generate high amounts of wastes (Di Donato *et al.*, 2017; Teixeira *et al.*, 2018). These types of wastes are sources of polyphenol compounds.

Environmental Perspectives

It is essential to keep the earth clean for the next generations. Use of carbon-resources materials such as fossil resources (coal, oil, and natural gas), mainly yield in CO₂ emission and increase in pollution, because environmental disorders become more serious (Fomin and Guseev, 2001; Golomb and Fay, 2004; Sudesh and Iwata, 2008). Lignocellulose-based wastes accumulated in large quantities in nature every year resulted in environmental problems (Mishra and Thakur, 2015). Accumulation of forest and agriculture residues and food and beverage wastes without any processing or use of harmful processes such as burning and incineration also yield in environmental problems (CO₂ and heat generation) (Lee and Lin, 2007). Employing food wastes (FWs) for ethanol production yields in global greenhouse gas control, local or regional solid waste and water quality control (Moon *et al.*, 2009). In addition, employing FWs could be a beneficial alternative to conventional incineration and landfill disposals of FWs, which generated second environmental problems such as toxic or greenhouse gas emission, and underground-water contamination by leachates, respectively (Moon *et al.*, 2009). Traditional extraction for the recovery of the value-added materials such as phenolic compounds from vegetable and fruit wastes by toxic (methanol, ethanol, and other organic) solvents may also cause serious environmental problems (Antuono, 2009). In addition, long-term exposure of chemicals such as silica dust have been shown to increase risk of heart disease (McCarthy *et al.*, 2012). The effects of exposing human lung’s sub-mucosal cells to SiO₂ having various sizes (10, 150, and 500 nm),

for 2–24 h *in vitro* have been also studied (McCarthy *et al.*, 2012). The nano-toxicity of 10 nm SiO₂ on the sub-mucosal cells is associated with inflammation. Toxic effects was not observed from amorphous silica with 150 and 500 nm (Kasaai, 2015; McCarthy *et al.*, 2012). Smoke was formed by burning of straws, where it is harmful to people and animals. In addition, remaining all of the stovers and straws in the fields have negative impact on the environment, soil fertility, and its structure as well (Lopez-Bellido *et al.*, 2014; Maiorella, 1985). Various sources of plant-based waste feed stocks as the raw materials have been used for conversion into value-added components. The conversion procedures respecting environmental issues may not have adversely impact to the human food chains (Hossain *et al.*, 2017). In California, there has been much work, with limited success, in trying to develop markets for rice straw as a reactant to its burning (Nelson *et al.*, 2011). In conclusion, it would be an environmental benefit to recover value-added materials from renewable wastes using those procedures, considering environmental concerns, instead of using fossil fuels, and different toxic solvents.

Hazardous chemicals may cause long-term detrimental health effects. There are several types of hazardous chemicals (carcinogens, reproductive and systemic toxins, neurotoxins, immune and dermatologic agents). These compounds may cause physical and/or health risks (Eisler, 2007). Depending on the type of the hazardous involved, chemicals may cause cancer, birth defects, induce genetic damage, cause miscarriage, injury and death from relatively small exposures.

Wastes generated from different resources those can be converted into useful materials by different methods. Three different platforms have been employed for conversion of wastes, biomass or components of biomass into value-added materials as follows: Chemical; physical (thermochemical; supercritical fluid, “SCF”; and supercritical water, “SCW”), and biochemical procedures. Each platform has specific characteristics for the commercial processing, including range of feed-stocks and products, co-products, cost, scale, and stage of technology development (Nelson *et al.*, 2011). Therefore, it has become considerable economic interest to develop processes for effective treatments and employing them for their conversion into useful products (Akhtar *et al.*, 2015). Expressions and their corresponding abbreviations appearing in this manuscript are listed in Table 1.

High degree of crystallinity of cell walls (cellulose and hemicellulose) and their protection by lignin make very difficult for the accessibility of cell wall components by different procedures. The pretreatment would facilitate the accessibility to the cell walls by different methods. All of these methods should make the lignocelluloses available to the different attacks, where crystallinity of cellulose, its accessible surface area and protection by lignin and hemicellulose are the main factors in order to obtain an efficient hydrolysis. In addition, the efficiency and cost of the further processing were improved and reduced, respectively. The pretreatment methods include milling, irradiation, microwave, steam explosion, supercritical CO₂ and its explosion, alkaline hydrolysis, liquid hot-water pretreatment, wet oxidation, diluted- and concentrated-acid hydrolyses, and biological pretreatments (Taherzadeh and Karimi, 2008). Most of pretreatment procedures have diverse advantages, which make them suitable for industrial applications. Pretreatments using dilute acid and hot water are relatively intensive (Eggeman and Elander, 2005), whereas biological pretreatment are extremely slow (Sun and Cheng, 2002). Some technological (energy balance, solvent recycling, corrosion, environmental) should be taken into account in the selected procedures (Taherzadeh and Karimi, 2008).

In order to convert wastes containing carbohydrate polymers into fermentable mono-saccharides effectively, pretreatment must be initially applied on the wastes produced in forestry, agriculture and food to break apart the firm structures of cell wall components. During the last few decades, various approaches have been used as pretreatments for fermentable sugars (Alvira *et al.*, 2011; Gu *et al.*, 2012; Yu *et al.*, 2014; Isikgor and Becer, 2015; Min *et al.*, 2015). Each pre-treatment has shown to have unique advantages

Table 1 Abbreviations appeared in manuscript

Abbreviation	Expression, term
CHG	Greenhouse gas
DSFM	Deproteinized sunflower meal
FW	Food waste
H ⁺	Hydrogen ion or hydronium
HP	High pressure, hot pressurized
HPHT	High pressure high temperature
NFC	Nano-fibrillated cellulose
OH [−]	Hydroxyl ion
OSA	Octenyl succinic anhydride
PLA	Polylactic acid
SBCFE	Sub critical fluid extraction
SBCW	Sub-critical water
SCFE	super-critical fluid extraction
SCF	Supercritical fluid
SCFs	Supercritical fluids
SCW	Super critical water
TOC	Total organic carbon
WRF	White-rot fungi

and disadvantages. Rapidly growing polymer wastes yield in a demand to apply environmentally friendly methods for their conversion. Biodegradable polymers could be derived from renewable resources, e.g., cellulose, starch, chitosan, zein, and poly-lactic acid (PLA) (Ray and Cooney, 2018).

Conversion Methods

Chemical Methods

Lignocellulose can be destructed by chemical means (Taherzadeh and Karimi, 2008). Since the objectives of this study were to choose conversion procedures without any negative impact on environment, thus, dilute and edible acids or dilute bases were used for chemical conversions (Belitz *et al.*, 2009). Concentrated acids or bases and organic solvents have not been used in this study. These materials may cause environmental harms. In the production of chitin, protein and after calcium carbonate components were separated from crustacean shells. Separation of proteins (deproteinization) is performed by their treating with a diluted aqueous NaOH, and calcium carbonate component of shells (demineralization) is separated by dissolving in a dilute HCl at ambient temperature, while the solution is stirring continuously. The demineralization and deproteinization are repeated to remove all inorganic components and proteins in the crustacean shells. Proteins, calcium chloride, and carotenoid pigments are side products obtained from isolation of chitin (Van Luyen and Hough, 1996). Chitin is not soluble in most common organic solvents. Deacetylation of chitin, or introduction of alkyl chains, hydroxyl or carboxyl groups into chitin results in an improvement in its solubility, which promotes processing, and thereby widening its practical applications (Van Luyen and Hough, 1996). Lignocellulose can be also destructed by chemical means (Taherzadeh and Karimi, 2008).

Biochemical Method

Biochemical technology refers to molecular transformations using enzymes and micro-organisms. It is often accompanied with energy efficiency and product specificity (Nelson *et al.*, 2011). Biochemical processing, sometimes refers to the conversion of C6 and C5 sugars or carbohydrates derived from biomass through fermentation process to biofuel and bio-based chemical products. The conversion of the major component of natural renewable resources into ethanol is given in Fig. 2.

Micro-organisms play active roles in degradation of biological wastes. Anaerobic digestion involves different sets of micro-organisms with highly specialized metabolic activities. Different biochemical procedures result in almost complete degradation of organic materials present in the wastes. The diversity and distribution of the micro-origins are of critical importance to the stability and performance of the reactants (Schauer-Gimenez *et al.*, 2010). A group of filamentous fungi (white-rot fungi, WRF) are able to break down lignin (the most resistant component of plant cell walls to degradation process) into CO₂ (Joy *et al.*, 2016). Pretreatment (delignification) plays a critical role in enzymatic hydrolysis of forestry and agricultural wastes by different enzymes to achieve glucose and xylose. In the pretreatment procedure, enzymes can depolymerize cell walls (cellulose and hemicellulose) into

Fig. 2 Conversion of the major components of renewable resources into ethanol.

monomeric sugars. A pre-treatment for oil and fat industrial waste products (de-proteinized sunflower meal, DSFM), was proposed as an effectiveness procedure for their microbial conversion and based on the principles of green chemistry. Three factors such as amount of wastes per unit of the desired product, the amount of hazardous substances used in the pretreatment process, and process efficiency are involved in the proposed method (Makarova *et al.*, 2017). The proposed method was based on the experimental data obtained by chemical hydrolysis and pre-treatment process of DSFM comprising both chemical and enzymatic hydrolysis. The optimal DSFM pretreatment conditions were selected based on the calculated amounts of the process efficiency (Makarova *et al.*, 2017). Lignocellulose can be destructed by enzymes or micro-organisms as a preferred environmental friendly method in comparison with chemical or physical procedures (Taherzadeh and Karimi, 2008). Polysaccharides (cellulose and hemicellulose) can be also destructed by enzymes or micro-organisms into simple sugars, organic acids, acetone and glycerol (Joy *et al.*, 2016; Tomme *et al.*, 1995). Many micro-organisms are able to degrade cellulose and hemicellulose, while micro-organisms have consumed them as carbon and energy sources (Joy *et al.*, 2016).

Food waste (FW) is recognized as an environmental pollutant. However, it is as a valuable substrate containing large amounts of organic materials (soluble sugars, starch, cellulose, proteins, amino acids, fats, oils), and inorganic acids. A comparison evaluation of glucose yields of the FW broth pretreated with amyloglucosidase, carbohydrazase, and a mixture of both enzymes revealed that a higher glucose yield was obtained, when the enzyme mixture was used (0.46 g g^{-1} of dry FW), in comparison with only amylo-glucosidase (0.41 g g^{-1} of dry FW) or carbohydrazase (0.35 g g^{-1} of dry FW) was used. A high ethanol yield (0.23 g g^{-1} of dry FW) was obtained after 15 h of fermentation by *Saccharomyces Cerevisiae* (a species of yeast). The FW broth was hydrolyzed by the enzyme mixture. The yield was estimated to be nearly equivalent to the ethanol yields of lignocellulose biomasses (Moon *et al.*, 2009). Ethanol yield (expressed as ratio of the amount of ethanol produced to the amount of the mass of dry FW) depends on the original of wastes (FW, household waste, starchy biomass, i.e., molasses, sugar cane, corn, wheat, rice, rye, barley, and potato, lignocellulose biomass, i.e., bagasse, corn stover, wheat straw, aspen, willow, and spruce) (Moon *et al.*, 2009; Nakamura and Sawada, 2003; Thomsen *et al.*, 2003). The ethanol fermentation depends on the salt concentration (Hirasawa *et al.*, 2006; Moon *et al.*, 2009). The use of FW for ethanol production by enzymatic hydrolysis and ethanol fermentation by *Saccharomyces cerevisiae* suggests a promising practical approach to prevent environmental pollution (Moon *et al.*, 2009).

Rice straw was converted into nano-fibrillated cellulose (NFC) by a combined procedure of physicochemical pre-treatment and successively enzymatic hydrolysis. The NFC, is characterized by a long and distinct fibrillated cellulose, with a wide of 30–200 nm, exhibiting excellent water retention capacity ($20 \text{ g water g}^{-1}$), and swelling capacity (105 mL g^{-1}) (Yan *et al.*, 2018). Hydrophobic groups (octenyl succinic anhydride, OSA) were grafted onto the surface of NFC to prepare an innovative OSA–NFC as a dietary fiber with enhanced health benefits (such as bile acids, cholesterol, nitrite ion, and oil or fat adsorption) to increase adsorption capacity for oil *in vitro* ($17.8 \text{ g oil g}^{-1}$ fat adsorption after digestion model) and *in vivo* (almost $500 \text{ mg fat g}^{-1}$ feces of rats). OSA–NFC was used as a high-quality dietary fiber with a strong ability to absorb oil to help regulate body weight, representing an innovative way of transforming biomass into value-added products (Yan *et al.*, 2018).

Composting technology

Composting is the biological decomposition of organic materials under controlled aerobic conditions (Epstein, 2001). It can involve both procedures with mesophilic and thermo philic temperatures (Epstein, 2001). Over 80 microorganisms have been identified in composting (Epstein, 1997). The ultimate goal in composting is to produce a humus-like material, which is an excellent soil conditioner and can be used for numerous horticultural and agricultural applications (Epstein, 2001). Physico-chemical properties (moisture content, water retention, infiltration and permeability of water, structure, cation exchange capacity) of soils were improved using materials obtained from composting (Epstein, 2001). In other words, the composting materials can be used as a soil conditioner. The materials listed below are some of the feed-stocks that have been composted (Epstein, 2001): (i) Materials obtained from leaves; (ii) food wastes generated at homes, restaurants and food industries during different processes; (iii) coated papers and cardboards; and (iv) biodegradable polymers such as biodegradable plastic bags (Epstein, 2001). Some of them have been used in food packaging.

Many factors affected the composting process as follows: (i) Oxygen; (ii) moisture; (iii) temperature; (iv) concentration of H^+ or pH; (v) nutrients mainly carbon, nitrogen, and phosphorus; (vi) particle size and surface area; and (vii) chemical and physical nature of the feedstock materials (Epstein, 2001). The rate and extent of microbial decomposition of organic compounds, and biodegradation of polymers/plastics depend on the above-mentioned factors (Epstein, 2001). The efficiency of biodegradation is dependent upon the feedstock, the system, and maximizing the microbial system (Epstein, 2001). Composting provides an alternative method for managing agricultural, forestry, and food wastes. Description on different methods of composting and resulting products are out of the objects of this study. A review article on various composting methods, their applications, the advantages and disadvantages of composting in food processing industries have been found elsewhere (Schaub and Leonard, 1996).

Biofuel production

Fuels as energy sources for engines can be produced by fossil or agricultural resources (Golomb and Fay, 2004; Hettenhaus, 2011; Taherzadeh and Karimi, 2008). Due to different reasons and disadvantages of fossil fuels, biofuels were replaced (Taherzadeh and Karimi, 2008). Various sources of plant-based waste feed stocks as the raw materials have been used for the bio-ethanol production (Hossain *et al.*, 2017). Most of ethanol production is fermented using hexose sugars present in cane syrup and corn (Lin and Tanaka, 2006). The following components of renewable biomass have been used to produce fuel products (ethanol and

biodiesel, fatty acid methyl ester, FAME): (i) Cellulosic materials (cellulose or lignocellulose); (ii) starch feed-stocks (from corn). Starch (other than corn) from crop residues (iii) sucrose feed-stocks (sugarcane or sugar beet); (iv) triglycerides feed-stocks (oilseeds); (v) vegetative waste materials; (vi) foods and yard wastes (Kramer and Belanger, 2011). Biofuels mainly ethanol produced from corn starch, and cellulosic materials (Hettenhaus 2011; Taherzadeh and Karimi, 2008). The FW is a promising substrate for ethanol production via enzymatic hydrolysis and batch ethanol fermentation (Moon *et al.*, 2009). Japanese policy has shifted toward cellulosic feed-stocks (Bacovsky *et al.*, 2009; Procentese *et al.*, 2016; Zhao *et al.*, 2012). The target of displacing 10% of the domestic consumption of fossil fuels by around 2030, is based on the abundant unused biomass resources in Japan, mainly crop and forestry residues. Japan was one of the first countries to process wood for ethanol production (Tang *et al.*, 2006). In Brazil, petroleum-based fuels are considered as an alternative to biofuels. Brazil continues to pursue a balanced approach between the development of fossil and bio-fuels with consideration for environmental impact, feedstock production, food supply, and national security (Kramer and Belanger, 2011). Over the last two decades, wheat straw has been used for the development of cellulosic ethanol. Iogen is one of the world's largest companies in developing, designing, and scaling-up cellulosic biofuel technology (see "Relevant Websites section"). This company transforms cellulosic biofuels into reliable and cost-effective fuels for today's cars and trucks. Iogen's cellulosic biofuels technology incorporates all of the necessary steps required to convert a wide variety of cellulosic feed-stocks into ethanol and other biofuels. Iogen (see "Relevant Websites section") is used wheat straw as a major raw material. The company is planning its first commercial facility in Saskatchewan (Canada) that will utilize cereal straw feed stocks (Nelson *et al.*, 2011).

There are four steps for the conversion of biomass to ethanol: (1) Pre-treatment to remove lignin and hemicellulose; (2) enzymatic hydrolysis of cellulosic wastes to sugars (3) fermentation for ethanol production; and (4) purification of ethanol and other products (Miyamoto, 1997). The pre-treatment step has a positive impact on the amount and type of enzymes that are required for hydrolysis of cellulosic wastes to sugars (Howard *et al.*, 2011). Pretreatment is a well-investigated process for ethanol production from lingo-cellulosic materials (Taherzadeh and Karimi, 2008). Several pretreatment procedures have been presented for lignocelluloses and waste materials in order to improve ethanol or biogas production. All these methods should make the lignocelluloses available to the enzymatic attack.

Conventional fermentation (yeast fermentation), have been selected as an economical procedure for conversion of waste biomass-into-bioethanol. This is because, the "key fermenting agent" yeast, is readily available in local and international markets. It is more cost-effective in comparison with other fermentation agents. Furthermore, yeasts are natural materials having fermentation capability and no chemical hazardous wastes are produced. Ligno-cellulosic wastes were also converted into biological compounds using different types of yeasts and fermentation processes (Hossain *et al.*, 2017).

Fermentation processes were employed to produce ethanol from can juice, sugarcane molasses (Kramer and Belanger, 2011), and cellulosic agricultural wastes (straw obtained from wheat, rice, barley, rye, corn and cobs). Pre-treatment was used to increase efficiency of enzymatic saccharification followed by alcohol fermentation, and to increase the accessibility of cellulose to cellulases (Huang *et al.*, 2017). The sugars are then converted into ethanol by the yeast fermentation. As the second-generation of biofuels, ethanol derived from lingo-cellulosic feed-stocks eliminates the food-fuel issue associated with sugar/starch feed-stocks and has also been shown to have a much more favorable net energy balance and lifecycle GHG reduction than corn (starch-based) ethanol. Within the "biochemical platform" other research is also developing new bacterial organisms and genetically modified yeasts were used to convert both C6 and C5 sugars to other biofuel and chemical products, with perhaps the most advanced efforts directed to produce butanol, an important industrial chemical and possible second-generation biofuel (Nelson *et al.*, 2011).

Physical Methods

Thermal degradation

A thermal treatment is defined as a treatment of a compound in a device, when the temperature is elevated as the primary means to change the composition or characters (chemically, physically, and biologically) of the compound. The major reduction in molecular weight occurred initially in thermal heating of polysaccharides (Belitz *et al.*, 2009; Fennema, 1996). No change in molecular size was observed after further heating. Incineration research for solid waste destruction has been fairly minimal the mid-1970s. The basic principle of solid waste incineration is similar to that of conventional fossil fuel combustion (Lee and Lin, 2007). Combustion or incineration is a very complicated subject.

Thermal degradation of polymers is associated with a series of chemical reactions via chain scission. The chain scission is usually followed by multistep free-radical mechanisms (initiation, propagation, and termination) (Ray and Cooney, 2018). Thermal degradation of polymeric materials generally implies the associated changes at inert atmospheric conditions. Under normal atmospheric conditions, oxygen plays a crucial role in the degradation process. The decomposition of biopolymers is accelerated by the presence of oxygen (Ray and Cooney, 2018). Lignocellulose can be destructed by heat (Taherzadeh and Karimi, 2008). Decomposition of most biodegradable polymers starts at an early stage, followed by a multistep degradation. In the presence of air, the glass transition temperature (T_g) (it is the critical temperature that separates glassy behavior from rubbery behavior. Many amorphous solids, including natural polymers and biopolymers, exhibit glass transition temperatures), profiles of these polymers look quite similar to that obtained in an inert atmosphere, except the primary degradation starts at comparatively a lower temperature (Cowie and Arrichi, 2007).

Fig. 3 Hydrolysis of cellulose.

Hot pressurized method

Hot pressurized fluids

A possible alternative to hydro-distillation or solvent extraction could be represented by the use of sub- or super-critical fluid extraction (SBCFE or SCFE) technique. It is based on the utilization of a fluid at sub- or super-critical conditions (Antuono, 2009). For instance, supercritical carbon dioxide has been used for decaffeination of coffee (Zosei, 1978). High pressure (HP), induced different changes (inactivation of microorganisms or enzymes, denaturation of proteins, and conversion of raw materials into useful components). These changes correlate with the food safety, and the food quality (Claeys *et al.*, 2003).

Hot pressurized water, near critical water and sub-critical water

Water is used in food industries as a safe and a non-toxic medium. Under different pressure and temperature conditions, it plays an essential role in producing value-added products from wastes generated in the land or marine. Hot pressurized water has a high reactivity. Hydrolytic reaction is a common process that occurs in water under high pressure-high temperature (HPHT) conditions. Raw materials (A-B) is hydrolyzed by water according to the following reaction (Brunner, 2009a,b):

The above equation shows a chemical reaction (a chemical reaction is a rearrangement of reactants to create different substances as products). The illustrated equation is a generation form of a hydrolysis reaction, where water (H-OH) is a reactant and another reactant (A-B) can be a component of a waste (from example, cellulose) as shown in Fig. 3:

The products of the above reaction are glucose and P1. The P1 has a similar structure of cellulose and its size is smaller than that of the original cellulose. The reaction can be continued with the product P1 as a reactant in a similar fashion as the above-mentioned (BeMiller, 1967; Kasaai *et al.*, 2013; Lazar *et al.*, 1989; Timell, 1964; Zaikov, 1975).

Water under HPHT with a low viscosity and a high diffusivity enhances reaction rates. Hydrolytic reactions occurred in the medium of hot pressurized water are often accompanied with thermal reactions (pyrolysis). The higher the temperature, the greater is the extent of thermal reactions. Either H^+ or OH^- ions generated from water under different temperature and pressure conditions play as a reactant role for fragmentation of biopolymers. The availability of protons increases by dissolving CO_2 in water (Brunner, 2009a,b). The reactions result in smaller macromolecules, oligomers and monomers. Large macromolecules of biopolymers may not be useful as much as the fragmented samples (smaller macromolecules, oligomers and monomers). The fragments containing large amounts of accessible nutritional components can be used as foods for humans. Abundant polysaccharides (such as cellulose and starch) or materials containing proteins can be hydrolyzed, under HPHT conditions and converted into smaller macromolecules, oligomers and monomers (mono-saccharides and amino acids). Under HPHT conditions "concentration of H^+ and OH^- as well as the ion product for water" increases. Change in concentration of H^+ or OH^- influences the results of acid or base hydrolysis (Arai *et al.*, 2001). Using hot pressurized water, polysaccharides, lipids and proteins have been extracted or decomposed. Polysaccharides (starch, cellulose, hemicelluloses, chitin, chitosan, etc.), and materials containing proteins (mainly from animal tissues: Skin, hair, feathers), can be transformed into smaller macromolecules, oligomers and monomers (mono-saccharides or amino acids) under HP conditions (Brunner, 2009a,b; Kasaai *et al.*, 2003; Knez *et al.*, 2018; Lamoolpha *et al.*, 2006). Hydrolysis of polysaccharides and proteins under hot pressurized water resulted in glucose and amino acids, respectively. Glucose and amino acids particularly essential amino acids are food components (Belitz *et al.*, 2009; Berg *et al.*, 2002; Brunner, 2009a,b).

Supercritical water

Under supercritical conditions, water acts as a medium or a reactant, and oxygen as an oxidizing agent. Under these conditions, water exhibits gas-like diffusion along with a high liquid-like collision rate, and the oxidation process takes place in a homogeneous mixture (Brunner, 2009a,b).

Cellulose has been completely converted into smaller molecules under SCW conditions at 400°C. Most of products obtained from cellulose decomposition were glucose, fructose, and oligomers of glucose (cellubiose, cellotriose, cellotetraose, cellopentaose and cellohexasose). Hydrolysis of cellulose under SCW conditions is a promising technology (Arai *et al.*, 2001). Under SCW conditions, combination of extraction and decomposition of polysaccharides, proteins and lipids can be occurred (Arai *et al.*, 2001; Brunner, 2009a,b). Higher efficiency, environmental more safety, and superior quality are the major advantages of extraction by SCF over the conventional extraction. Near critical and SCW have been used to enhance extraction affinity of value-added compounds

(proteins, amino acids, essential oils, oils, fatty acids, carbohydrates, and phenolic compounds) from natural sources (Knez *et al.*, 2018). Production of proteins and amino acids is strongly influenced by temperature (Lamoolpha *et al.*, 2006). Degradation of biomass under sub critical water (SBCW) or SCW cannot be easily described by well-defined single reaction steps, due to the complex degradation pathways of the products (Sinag *et al.*, 2010).

Oxidation procedure of wastes under SCW conditions is an alternative procedure to treat different wastes with a high water content like garbage. Materials from groups of vegetables, meats and fishes were easily oxidized under SCW conditions (Jin *et al.*, 1999). Fatty meats “particularly beef suet” were most difficult to decompose among different components of garbage (Jin *et al.*, 2001). Treatments of carrot and beef suet under SCW conditions were carried out in a bath reactor system with H_2O_2 as an oxidant at a temperature between 400 and 450°C and reaction times from 10 s to 10 min. The results showed that the oxidative decomposition of carrots and beef suet proceeded rapidly and a high total organic carbon (TOC) decomposition of up to 97.5% was obtained at 420°C within 3 min, for carrots and at 450°C within 5 min for beef suet, when there was a sufficient supply of oxygen. The oxidation reaction on carrot and beef suet might be separated into a fast reaction at the early stage and a slow reaction at the latter stage (Jin *et al.*, 2001). The SCW is a good medium for an oxidation process, because oxygen and many organic substances are soluble in the SCW (Brunner, 2009a,b; Franck, 2000). Organic wastes are decomposed or oxidized under SCW conditions in the presence of oxygen (air) (Savage, 2009). Food ingredients with desirable sizes have been produced by fragmentation of large macromolecules using SCW. Water under above-mentioned conditions are not only reaction medium, but also is a reactant. Thus, water as a reactant leads to hydrolysis of reactants, leading to rapid degradation of complex biomass structure such as hydrolysis of cellulose to sugars (Sinag *et al.*, 2010). Global kinetics analysis is described that the early stage is an oxidative reaction of beef suet could be considered as the first-order reaction with respect to the concentration of organic carbon. Polysaccharides “major components of carrot” are initially hydrolyzed to glucose, and then, glucose is being oxidized. Triglycerides “the major components of beef suet” have been initially hydrolyzed to glycerol and carboxylic acids, followed by oxidative decomposition of the further products through consecutive reactions have been occurred.

Comparison of Various Methods of Conversion

Advantages and disadvantages of several methods are given in Table 2. A comparison evaluation of various methods of the conversion in terms of their effects on the conversion procedures (extraction, hydrolysis, decomposition, de polymerization), and from the standpoint of ease of preparation of the useful products, enables one to conclude as follows: (i) Various renewable (agricultural, forestry, beverage, food) macromolecules are decomposed by a variety of enzymes, and micro-organisms into smaller than that of the original ones; (ii) polysaccharides are degraded by acids or enzymes and yielded in a mixture of low molecular weight polysaccharides, oligosaccharides and mono-saccharides (Belitz *et al.*, 2009; Fennema, 1996); (iii) biochemical methods have advantageous over physical and chemical (acid hydrolysis) methods, because they are easy to perform at ambient temperature. These methods can be easily be controlled, due to their low reaction rates. The enzymes and micro-organisms are naturally exist in soils or commercially available with a low price. However, the efficiency of natural enzymes and micro-organisms are significantly lower than that of the commercial ones with a high purity; (iv) physical methods have advantageous over chemical methods, because they do not need chemical reagents, but the equipment for the physical processes are expensive. The incineration procedure (as a traditional, thermal, and a decomposition procedure) is an efficient one, however it is not an environmentally suitable approach. In addition, several useful organic compounds destroyed and may be converted into hazardous compounds; and (v) chemical methods are advantageous over enzymatic and physical methods due to the low cost of chemical reagents and relatively good and reasonable efficiency. However, use of diluted acids or bases as a hydrolytic reactant has a practical limit of conversion. In conclusion, depending on the procedure used and the reaction conditions employed, a variety of products can be obtained (Lee and Lin, 2007; Lin *et al.*, 2013).

Table 2 Comparison of different conversion procedures for wastes derived from land (agriculture, forestry, food, beverage) and marine sectors

Method/procedure	Advantages/performances	Disadvantages/limitations
Chemical	Does not need special apparatus; easy to perform, low cost for the chemical reagents; generally the efficiency of conversion is good. However, the efficiency and reaction rate depend on the concentration of chemical reagent and temperature of the reaction	Needs chemicals; generate hazardous wastes; negative impact on the environment
Biochemical (Enzymatic)	The efficiency depends on the purity of enzymes; better control of the process; natural enzymes and microbes are available in soils	Commercial enzymes with a high purity are expensive
Physical (hot pressurized water, SBCW, SCW)	Does not need chemicals; short time is needed to process, environmentally are safe	High amounts of energy are needed; high technology is required
Physical (Thermal)	Does not need chemical reagent	A part of energy/heat is lost; the conversion products oxidized by oxygen (air); negative impact on the environment

Table 3 Conversion procedures for different types of wastes, by products and their applications

Source of wastes	Type of wastes	Conversion process	By products	Applications	Remarks
Agriculture and forestry	Leaves	Size reduction physically (by mill); mix the powdered leaves with soils	Organic soils	Fertilizers for soils and plants	Leaves mainly contain organic compounds
Agriculture and forestry	Leaves and Peels	Extraction	Phenolic compounds, antioxidants, vitamins	As food additives, antioxidants, vitamins	Leaves from different sources contain different value-added components
Agriculture	Rice straw	Separation of silica from rice straw (digestion with NaOH solution and followed by an acidification step)	Silica,	Silica as a filler for coatings and packaging's	Rice straw contains sufficient amount of silica
Agriculture	Straws from cereal grains (wheat, rice, oat, rye, and barley),	Enzymatic hydrolysis; fermentation	Sugars (glucose, xylose)	As by products for foods; as raw materials for bio-fuels (ethanol).	Straws can be used as animal bedding, feeds,/ fodder, basket-making
Agriculture, forestry, and food	Straws, wastes containing starches or lingo-cellulosic biomass from different crops food, and yard resources	Hydrolysis, and fermentation	Biofuels (ethanol, propanol, butanol)	As energy source for engines;	Starch-based biomass is major components of crop and some plant wastes Ligno-cellulosic biomass is, renewable resources on the Earth and obtained from forest and agriculture residues

Value-Added Materials From Different Wastes

Different naturally occurring and food wastes can be used for production of value-added components as follow: (i) C6 and C5 sugars (glucose and xylose). These sugars are monomer units of carbohydrate polymers (Belitz *et al.*, 2009; Jager and Büchs, 2012); (ii) biofuels (mainly ethanol), organic acids, and food additives (Mishra and Thakur, 2015); (iii) leaves may be converted into smaller sizes. The smaller sizes of leaves can be mixed with normal soil and produced organic soils. The organic soils may be used to fertilize the normal soils for various plants. Plant leaves like dark green leafy vegetables “are rich sources of phenolic compounds, and lipid-soluble antioxidants”. Alpha-tocopherol (vitamin E) and beta-carotene (precursor to vitamin A) were derived from leaves. Their recovery from plant leaves could provide a valuable source of natural vitamins. Alpha-tocopherol was recognized as the main antioxidant compound derived from leaf extracts of 15 plant species (Booth, 1963; Mukhopadhyay, 2000). Tocopherol content could be enriched by hexane extraction up to 4.7% (Booth, 1963; Mukhopadhyay, 2000); (iv) corn stover, straw and leaves are major components of forest and agriculture residues. Corn stover and straw may be discarded in the farming fields to degrade in the nature, burning to generate energy as heat, or may be used as a cattle feed (Lopez-Bellido *et al.*, 2014; Maiorella, 1985); (v) straw, an agricultural by-product (the dry stalks of cereal plants), obtained from the harvested crops, after the grain and chaff have been removed. Straw makes up about half of the yield of cereal crops (wheat, rice, barley, oat, rye). It has many applications “including fuel, livestock bedding and fodder, and basket-making” (Hettenhaus, 2011). The straw of rice is rich in silica content. Silica obtained from the straws has been used as a filler to make composite, construction, and packaging materials (Nelson, *et al.*, 2011). Wheat straw has been used for animal bedding, fodder, and feeds (Nelson, *et al.*, 2011); (vi) plant and food wastes are the most common ones, in which their applications are progressing (Schauer-Gimenez *et al.*, 2010). The extracts materials from citrus wastes (leaves and peels) were efficient materials for the stability against oxidative reactions of the Kraft Papers. The kraft paper treated by citrus wastes can be used for food coatings and food packaging to protect foods from moisture and oxygen deteriorations and to extend their shelf-life (Kasaai and Moosavi, 2017). Oxygen and water barrier properties and antioxidant activity of the treated papers were improved; and (vii) in some cases, the heat generated by incineration can be used to generate electric power. The different wastes were also employed to convert energy such as heat and electricity, for instance, residual sugarcane bagasse was used to generate electricity in Brazil (Gopale and Kammen, 2009). The waste materials are converted into “ash, flue gas and heat” by incineration process. The ash is mostly made of inorganic compounds and may take the form of “solid lumps or flue gas” (Lee and Lin, 2007). Conversion procedures for different types of wastes into “by products and their applications” are presented in Table 3.

Conclusions

The following conclusions are drawn: (1) Wastes generated in the land (forestry, agriculture, beverages, and food), marine, and food sectors are initially described; (2) several substances potentially present in the wastes can be converted into useful

components by pretreatment and further major processing as follows; (i) chemical; (ii) physical (thermal, super-critical fluids, supercritical water); and (iii) biochemical (enzymes, and microorganisms). This study mainly focused on the procedures with environmental perspectives. Biochemical (hot pressurized water, SBCW and SCW) procedures represent as safe and green ones; (3) some useful products obtained from different wastes are "different components of sugars in particular (glucose and xylose), polyphenols as antioxidants and oxygen scavengers, beta-carotene (precursor to vitamin A), alpha-tocopherol (vitamin E), biofuels (ethanol), soil and plant fertilizers, and silica from straws for coatings and packaging composite materials applications" and (4) the final products can be used as foods, feeds, fertilizers of soils and plants, fillers, or animal beds. The value-added products can be also employed for other commercial applications as well.

Future Perspectives

Applications of desirable methods as well as emerging processing with environmental perspectives to convert renewable wastes into value-added components offer a good opportunity to avoid further destruction and pollutions of this planet. To protect this planet for the next generations, all of governments from different countries, commodity groups, manufacturers, research groups, consumers, and in general, human beings must follow a desirable direction for conversion of various wastes into value-added products.

Introduction

3D printing, a disruptive manufacturing technology, has emerged as an innovative approach to fabricating electrochemical energy storage (EES) devices from nanoscale to macroscale, providing great opportunities to accurately control device geometry (e.g., dimension, porosity, and morphology) and structure with enhanced specific energy and power densities. Moreover, the “additive” manufacturing nature of 3D printing provides excellent controllability of the electrode thickness with much simplified process in a cost-effective manner. With the unique spatial and temporal material manipulation capability, 3D printing can integrate multiple nano-materials in the same print, and multi-functional EES devices (including functional gradient devices) can be fabricated (Shaheen *et al.*, 2005; Sun *et al.*, 2014). The direct material deposition characteristics of these two processes enable them to print on a variety of flat substrates, even a conformal one, well suiting them to applications such as wearable devices and on-chip integrations. Fused deposition modelling (FDM) is one of the efficient process among 3D printing techniques which have the potential to print recycled plastic solid waste as per tailor made applications (Kumar *et al.*, 2017a,b, 2018; Singh *et al.*, 2016, 2018a,b,c). It has been reported that modified two-step in-situ reduced method is used to synthesize reduced graphene oxide (r-GO) (whose electrical conductivity can reach up to 600 Scm^{-1}) which can be easily blended mechanically/ chemically in thermoplastic materials. Some studies have reported that polylactic acid (PLA) and r-GO was mixed by melt blending. These types of reinforcements in plastic solid waste can be used for addressing the waste management issues. The 3D print-used composites filaments with the diameter of 1.75 mm are usually fabricated through melt extrusion. The orientation of r-GO occurs during the extrusion process, which contributing to increase the conductivity of the filaments. The composite also exhibit superior mechanical properties like elastic modulus, ultimate tensile strength may be because of meta material formation (Leigh *et al.*, 2012; Guo *et al.*, 2013; Molina *et al.*, 2014). The printed 2D and 3D flexible circuits have strong interface bonding force between the layers. The filaments from 3D printer can replace the copper wire because of the high conductivity. This arbitrary 3D graphene-based structure printing technique may open a new prospect in electronic and energy storage fields. To create the micro battery, a custom-built 3D printer extrudes special inks through a nozzle narrower than a human hair. Those inks solidify to create the battery's anode (red) and cathode (purple), layer by layer. A case then encloses the electrodes and the electrolyte solution added to create a working micro battery. The inks contain nano-particles of a lithium metal oxide compound that give the anode the proper electrical properties. The printer deposits the inks onto the teeth of two gold combs, creating a tightly interlaced stack of anodes and cathodes (Gross *et al.*, 2014; Tekinalp *et al.*, 2014). After this the researchers packaged the electrodes into a tiny container and filled it with an electrolyte solution to complete the battery (Leigh *et al.*, 2012; Guo *et al.*, 2013; Molina *et al.*, 2014). Organic semiconductor based photovoltaic devices offers the possibility of manufacturing low cost photovoltaic technology that can be 3D printed by roll to roll printing techniques. Existing organic photovoltaic devices are currently limited to solar power conversion efficiencies of 3%–5% (Shaheen *et al.*, 2005).

Graphene is two dimensional materials which has extraordinary material characteristics like: high Young's modulus, ability to thermally and electrically superconductive (high mobility of charge and electron), surface insulating behavior and large aspect ratio for prototype fabrication. Graphite is a low cost raw source for extraction of graphene (Kumar *et al.*, 2017b). Graphene generally extracted via different methods of processing like; chemical vapour deposition (CVD), micromechanical exfoliation, and ball milling etc. (Su *et al.*, 2011; Calderon-Ayala *et al.*, 2017). FDM process as a 3D printing technique with feedstock prepared on twin screw extrusion process can be one of the best alternative for production of electrically conducting nano-porous polymeric composite materials for energy conversion and storage (Kumar *et al.*, 2018). Mechanical properties of FDM fabricated parts are highly dominated by their filament processing. The mechanical sustainability of the fabricated parts are dependent upon the nature of processing of the initial component (grinding, extrusion etc.). Barrel temperature, rotational speed and torque are some of the input variable during the filament processing which largely affects the mechanical sustainability of the FDM fabricated parts (Singh *et al.*, 2017a,b,c,d, 2018d). FDM is one of the economical ways for 3D printing of thermoplastic composite with nano-particles (with use of extrusion process) for development of energy conversion and storage devices. The 3D printed parts may be used in 4D applications as because non conducting thermoplastics have been made conducting with reinforcement of nano particles.

In this work a frame work has been proposed for FDM process based printing of electro chemical storage device from polymeric waste based nano-composite. The proposed methodology will lead to waste management (especially plastic solid waste) for sustainable manufacturing. This will reduce the cost of formation of dry cell which can be easily. The proposed process is cost effective since the material used in making cell as energy storage device is industrial waste (available in abundance) and can be used number of times. Hence it is highly commercially viable. Table 1 shows the merits and demerits of commercial and 3D printed ESD.

Table 1 Merits and de-merits of commercial and 3D printed ESD

<i>Conventional ESD</i>	<i>3D printed ESD</i>
(1) The commercial ESD (mainly commercial dry cell) comprises of different zones/sections of chemicals/salts for initiating a chemical reaction (for converting chemical energy in to electrical energy), which is being put in different forms like powder/paste/slurry in a zinc container resulting into compact structure (2) The advantage with conventional ESD is that since the chemicals/salts are in direct contact with each other, the chemical reaction is relatively fast and one can get high potential difference value	(1) Whereas the 3D printed ESD is directly printable in form of different layers which are assembled in series to provide required potential difference. Since different zones are printed and assembled the final structure is not that compact (2) Where as in 3D printed ESD the chemicals/salts are blended in thermoplastics, so the chemical reaction is little slow and one needs to add catalyst for initiating the chemical reaction But the advantage of 3D printed ESD is: (i) Design flexibility, that means any contour/shape of ESD can be printed (ii) No specific container for putting the chemicals/salts is required. (iii) As the 3D printed ESD are acting as container for chemicals/salts itself additional shell covering is required (iv) The 3D printed ESD are more thermally stable under extreme environment conditions (both hot and cold)

**Fig. 1** Construction of dry cell.

Conventional Dry Cell and Proposed Modification

Existing Dry Cell and its Construction

The concept of a dry cell was invented by French scientist G. Leclanche in 1868. As this cell is free from any liquid for its chemical reactions, so it is termed as dry cell. **Fig. 1** shows the basic construction of a dry cell which is composed of number of successive layers for the internal terminal known as carbon rod (positive electrode) to external terminal known as zinc terminal (negative electrode).

The carbon rod is placed in centre of the dry cell which is being covered by crushed coke and MnO_2 and bagged in the canvas material. The mixture of both is act as the de-polarizer. This de-polarizer material is providing the resistance to hydrogen bubble formation during chemical reactions. The de-polarizer is actions to take the electron during discharge and is basically an oxidizing agent. The paste of ammonium chloride and zinc chloride is act a electrolytic material to support the chemical reactions for energy formation. The electrolytic mixture is covered by saw dust and pitch compound to provide the ventilation to the electrolyte during chemical reactions. Every portion of the battery device has chemical reactions occurring in it. While a reduction reaction occurs at the carbon electrode, oxidation occurs at the zinc casing, which is the anode.

In Zinc-carbon dry cell, the carbon rod acts as cathode, whereas zinc acts as anode. The dry cell results in flow of electron as an oxidation reaction at zinc terminal whereas reduction reaction as carbon rod terminal

The zinc terminal is get oxidized by following oxidation half reaction;

At cathode, the MnO_2 is get reduced by following reduction reaction;

Overall reactions are represented as;

Here, one need to know that zinc chloride is another replacement of ammonium chloride, when ammonium chloride is replaced by zinc chloride then the cathode reactions can be followed as;

Then the overall reaction is processed as;

Unlike a wet cell, a dry cell can operate in any orientation without spillage, (as it contains no free liquid). The wet cells are in fragile glass containers with lead rods hanging from the open top and needs careful handling. A common dry cell produces the electromotive force of about 1.5V. Overall capacity of the dry cell is dependent upon the side reactions and active chemical content. Commonly Zn-C cells have small shelf life as Zn is attacked by NH_4Cl . The Zn container becomes thinner as the cell is used, as because Zn metal is oxidized to Zn^{+2} . When the Zn covering thins enough, ZnCl begins to leak out of the battery. The Zn casing in the dry cell gets thinner even when the cell is not being used, because NH_3Cl inside the battery reacts with the Zn.

Construction of New Dry Cell by 3D Printing

In this study, before printing a dry cell a filament can be developed by mixing different chemical/salts (nano scaled) used in conventional dry cell with acrylonitrile butadiene styrene (ABS)/or other commercially available polymeric waste by using twin screw extruder. After preparation of feedstock filament, it was fed into commercial FDM system (without change in any hardware/software of the system) which print a dry cell layer by layer. As a result, a complete dry cell is printed from a single work station (see Fig. 2).

Fig. 3 shows process flow chart for 3D printing of dry cell.

The reinforcement of chemical/salt with recycled ABS (collected from industrial waste) starts with different proportion/composition, which was poured in to melt flow index machine (as per ASTM D1238) to ensure fluidity/flow ability properties of

Fig. 2 Various zones of 3D printed dry cell.

Fig. 3 Flow chart for 3D printing of dry cell.

different reinforcement in polymer matrix. The experimental investigations were performed to set range of all proportions/compositions, so that their MFI values for different type of reinforcements remain close to each other. It has been observed in pilot experimentation that selected recycled ABS with MFI of 2.5 g/10 min resulted into MFI of 2.0–2.3 g/10 min with various reinforcement: (i) ABS + 50% Zn powder, (ii) ABS + 40% nano scaled NH_4Cl , (iii) ABS + 50% nano scaled MnO_2 , (iv) ABS + 10% nano scaled graphene. Due to modified range of MFI for all reinforced materials there is no requirement to change the parameters of FDM while printing of dry cell.

Performance Properties of Graphene Reinforced ABS Waste Composite

There are two basic methods available for mixing of graphene into polymer matrix: mechanical mixing and chemical mixing. The mechanical mixing is the process of mixing graphene into polymer matrix by using twin extrusion process in which granules of polymer matrix mixed with graphene through the compound screws of twin screw extrusion. In chemical mixing, granules of polymer and graphene are being treated under dissolution of chemical (As ABS is being dissolve in acetone solution) During pilot experimentation electrical and thermal conductivities of graphene reinforced ABS (prepared with chemical/mechanical means) were observed. It has been reported that chemical mixing of graphene reinforced ABS polymer matrix resulted in maximum electrical and thermal conductivities for ABS: graphene ratio of 75:25 at 100% infill density. So it is ascertained that mixing of graphene into polymer matrix largely influences the electrical and thermal characteristics.

Graphene is an extraordinary material that is now days used largely to produced nano-porous materials. Graphene also has inherent material characteristics like: excellent thermal and electrical conductivities, high mechanical strength and etc. In the proposed method of 3D printing for development of energy conversion unit a thermoplastic matrix used as main material. As ABS is having excellent moulding stability so this can be selected as for fabrication of conducting as well as non-conducting layers. ABS is a non-conducting material, but when reinforced with nano-sized graphene into its matrix the excellent thermal as well as electrical conductivities can be achieved. [Kumar et al. \(2017b\)](#) outlined that thermal as well as electrical conductivities of recycled ABS polymer matrix can be modified by reinforcement of graphene powder (See [Figs. 4\(a\)](#) and [\(b\)](#)).

Methodology for Electrochemical Dry Cell From Polymeric Waste

Initially the (chemical or mechanical) blend of nano sized reinforcement in ABS matrix in form of pallets was prepared. Pallets of blended nano sized reinforced ABS polymer was processed into the melt flow index (MFI) tester for ensuring the flowability in g/10 min of the blend as per ASTM D 1238 standard. The MFI value in g/10 min is selected based upon the FDM settings so that there is no need of change any hardware/software during printing for different types of reinforcement selected. If the MFI of different blended materials falls in the acceptable/similar range then the printing is performed smoothly. After establishing MFI of various blends, selected composition/blends are further processed on twin screw extrusion machine to prepare the feedstock

Fig. 4 (a) Thermal conductivity of graphene reinforced recycled ABS. (b) Electrical conductivity of graphene reinforced recycled ABS. Reproduced from Kumar, R., Singh, R., Hui, D., Feo, L., Fraternali, F., 2017b. Graphene as biomedical sensing element: State of art review and potential engineering applications. *Composites Part B Engineering* 134, 193–206.

Note: 75–25 and 90–10 is the proportion of ABS-Graphene in weight percentage. It has been observed that chemically processed blend of ABS-Graphene at 75–25 weight proportion is better from thermal and electrical conductivity view point.

filaments of 1.75 mm diameter. The design software is used to generate the required layers and design of the dry cell component. Finally at optimized input process variable settings, component of the dry cell are printed and assembled in a fashion given in Fig. 2. Further for investigation of performance of dry cell, output voltage, thermal analysis by differential scanning calorimetry (DSC) and mechanical properties needs to be ascertained.

In order to ascertain the stability of recycled ABS reinforced materials; at extreme temperature variations (in which ESD can work) the thermal condition of different zones has been monitored with DSC. For thermal analysis METTLER TOLEDO, Model DSC3, Swiss make with STAR^e (SW 14.00) software (as per ASTM E794–06(2012)) was used in air environment. Figs. 5(a) and 5(b) shows the DSC based thermograph for ABS: MnO₂ as 50:50 (curve 1), ABS: graphite fixed as 60:40 (curve 2) and ABS: ZnCl₂ + NH₄Cl as 60:40 (curve 3).

As observed from Fig. 5a, in two repeated heating cooling cycles, the T_g is above 95°C. Hence it can be ascertained that all the four zones of ESD can be successfully operated up to this temperature range. Further as observed from Fig. 5b the heat absorbed/released per unit g for all three different reinforcements (see curve 1, 2 and 3) is almost same, which signifies the stability of this material for high temperature application (around 95–100°C).

Cost Analysis

It should be noted that the recycled ABS is available at the cost of 1–2 US\$/Kg. The nano size MnO₂, NH₄Cl, graphene, ZnCl₂ is available commercially at the cost of 500 US\$/Kg. After blending of different reinforcements in ABS, out of 1 Kg material around

Fig. 5 (a) DSC graphs for glass transition temperature (T_g) of different reinforcement in ABS. (b) DSC graphs for energy absorbed/ released per unit g of different reinforcement in recycled ABS.

5000 pieces of dry cell can be printed. Hence the material cost per cell is estimated as 0.1 US\$, which is comparable to the cost of commercially available dry cell.

Following are some of the important features of the proposed dry cell as ESD in the context of modification of conventional technologies:

- Reduction in the manufacturing cost as major part comes from waste plastics.
- Increased safety while chemical reaction, as the traditional cell starts leaking after some time.
- Waste material management becomes easy as we know the dimensions of material printed at different ends.
- This cell can be used several times by changing the eroded material.

- Material can be used by recycling by its waste contents separately.
- The dry cell printed is more stable under extreme temperature conditions (both hot and cold).
- The user can have the control of changing the potential difference by changing the number of layers while printing.

Summary

Following are the observations from the present study:

The 3D printing of ESD by reinforcement of nano sized particles in recycled ABS is possible through FDM. For ensuring the flow ability of electrolyte salts and nano-composite (namely: MnO_2 , NH_4Cl , ZnCl_2 , Graphene, Zn etc.) reinforcement in waste/recycled ABS, ASTM D1238 is useful in deciding reinforcement proportions. This actually helps in 3D printing of nano sized reinforced particles without change in any hardware or software of the system. The DSC analysis of the different compositions/proportions ensures the thermal stability of dry cell under different temperature conditions. Overall the proposed methodology for 3D printing of ESD can lead to green cost effective solution.

Green and Healthy Alkaline Materials

Souad Al-Bat'hi, International Islamic University Malaysia, Malaysia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Green materials means, making healthy, safe and sustainable choices, especially in the way our bodies use energy, water, food intake, and also selecting engineering materials with improved properties and performance. These natural materials are local, renewable, and crucial to maintaining a sustainable healthy and safety life style. Our bodies need the green natural materials such as water, carbohydrates, proteins, amino acids, fat, vitamins, minerals, omega-3 fatty acids etc., to survive a healthy life without sickness and/or diseases. And our environment needs engineering materials that have a positive impact on the surrounding structures to survive a safely life without damages and disasters.

In this article we are concerning human health and to emphasize on how people can make the right diet choice and to avoid food that may have a negative impact on our body which is relevant to everyone. And also concerning human safety by emphasizing on how people can make the right choice of engineering materials to avoid damages and disasters.

Food is an integral component of life and human existence. Since the beginning of time humans have had to eat and to build to survive (Joyce *et al.*, 2013). Resources of food and engineering materials were green, natural, and abundant. The population growth in last several decades has made the need for sustainable production and processing technologies of materials, more important for the increasing number of humans.

The controversial here, is the processed food green, healthy, and advisable to be consumed by humans? To answer this question we need intensive investigation and testing. The challenge here is to convince them to live a green and healthy life by consuming green and sustainable materials.

The food that we choose to eat can have a direct impact on our ability to enjoy a healthy life, and the diet plays a major role in promoting a good health and it may have a long-term effects.

Is all foods we daily consume, green and healthy? This depends on the impact of a specific food whether positive or negative. The food that turns the medium of our bodies into alkaline has a positive impact and it is considered green and healthy food. On the other hand, that turns the medium acidic has a negative impact and considered unhealthy. Therefore, we should have a well control on our daily food intake by eating more alkaline and less acidic, or in other words, to alkalinize our food intake by following a good and healthy diet system. The question here is, why alkaline diet?

The alkaline diet is also known as the acid-alkaline diet or alkaline ash diet. Its premise is that our diet can alter the pH (power of hydrogen or potential of hydrogen) value or the measurement of acidity or alkalinity of our bodies. The conversion of food into energy (the metabolism process) involves a chemical reaction that breaks down a solid mass and releasing energy. When the food we eat burns, an ash residue is left behind known as metabolic waste which can directly affect our bodies' acidity. If we eat foods that leave acidic ash, it makes the blood more acidic and the body became vulnerable to illness and disease. Alkaline ash makes the blood more alkaline and considered protective and improve health (Joe, 2018). We are advised to alkalinize the diet by choosing the right variety of food. Finally we would say that life on earth depends on appropriate pH levels in and around living organisms and cells. Human life requires a tightly controlled pH level in the serum of about 7.4 (a slightly alkaline range of 7.35–7.45) to survive (Gerry, 2012).

The effect of acidity on engineering materials that is in direct contacts such as acid rain and the dry deposition of acidic particles contribute to the corrosion of metals such as iron bronze, and the deterioration of pents and stones such as marbles and limestone. These effects are seriously reduce the value of buildings, bridges, cultural objects such as statues, monuments and tombstones and cars.

What is pH?

pH is a number indicating the acidity or alkalinity of the blood or any other solution. It indicates the acidity and alkalinity by measuring the hydrogen ion concentration $[H^+]$ in the blood. If pH is lower than 7, the blood is more acidic, and if higher than 7 the blood is more alkaline. Blood is neutral when pH is exactly 7. The pH is notionally defined for any medium as the decimal logarithm of the reciprocal of the hydrogen ion activity $(a)_{H^+}$, in the medium as shown in Eq. (1) below:

$$pH = -\log_{10}(a)_{H^+} = \log_{10} 1/(a)_{H^+} \quad (1)$$

It is only for very dilute solutions that the pH can be directly related to proton concentration C_{H^+} as shown in Eq. (2) below (Karastogianni *et al.*, 2016):

$$pH = -\log_{10} C_{H^+} \quad (2)$$

pH is a measurable parameter, to measure it, there are two methods, the first one is by using an electronic device called a pH meter as shown in Fig. 1 below

Fig. 1 pH meter.

Fig. 2 Litmus paper strips chart and litmus paper strip.

The key parts of the pH meter are:

- (1) Solution being tested.
- (2) Glass electrode.
- (3) Thin layer of silica glass.
- (4) Potassium chloride solution.
- (5) Internal electrode.
- (6) Hydrogen ions.
- (7) Voltmeter converts the potential difference into a pH reading.
- (8) Reference electrode.

The second method is by a accrued estimate of pH in laboratories can also be performed by pH indicators called litmus paper strips for everyday use at home as well which allow the measurement of pH colorimetrically, through color changes. **Fig. 2** shows the litmus paper strips chart.

These indicators are dye-infused paper strips, which are dipped into the solutions and then removed for comparison against a color-pH key (*Karastogianni et al., 2016*), as in the chart of **Fig. 2**.

Basically, the litmus paper turns a slightly different color in solutions between pH 1 and 14 and, by comparing the paper to a color chart, we can read off the acidity or alkalinity without worrying how many hydrogen ions there are.

We can measure the pH of our body at home on daily bases by dipping the litmus paper into the saliva or urine. We should do that in the morning before eat or drink anything. When removed from the saliva or urine, match u p the color of the litmus paper with the color chart. It takes us 20–30 s. This determination of pH helps to balance our acid/alkaline diet.

Material Science and Materials Engineering

Materials science is an interdisciplinary field of science and engineering studying the relationship between the structures of materials and their properties and performance. Whereas materials engineering involves selecting materials, improving their properties and performance, lowering the manufacturing costs, developing new processing methods, and increasing their durability and utility. Basically, materials are the starting point of any project. The effect of acidity on engineering materials that is in direct contacts such as acid rain and the dry deposition of acidic particles contribute to the corrosion of metals such as iron bronze, and the deterioration of pents and stones such as marbles and limestone. These effects are seriously reduce the value of buildings, bridges, cultural objects such as statues, monuments and tombstones and cars.

An experimental study of chemical degradation effects on the mechanical behavior of sandstone in which the sandstone samples were immersed in acid solutions with different pH values to undergo chemical degradation. It is found that the chemical degradation induced the of elastic modules and compression failure strength. In addition to that, the creep deformation rate is enhanced by the chemical degradation (Wang *et al.*, 2016).

Another study on the effects of temperature (10, 20, 30) °C and pH level (1, 2, 0.5) of H₂SO₄ on the properties of concrete. In this study corrosion caused by H₂SO₄ attacks the concrete, resulting in significant economic losses and environmental problems. This research demonstrates a high correlation between the pH level or the Acidity of the solution and the rate of corrosion with respect to time (Mahmoodian and Alani, 2017). Accordingly, Engineering materials particularly the construction materials are exposed to Acidity and high pH level through acid rain and environmental humidity that creates many problems.

Most of the engineering materials come into direct contact with other materials and react chemically to each other that affect the materials properties such as corrosion resistance, Acidity, alkalinity, and many others. Corrosion is a chemical attack on a metal by its surroundings medium such as air, acid, bases, salt solution and so on. Due to the corrosion, metal starts getting converted into an oxide and the strength and life of the materials are reduced.

To decide whether the engineering materials are acetic or alkane, we should look at their pH value which varies from 0 to 14. Materials with pH of 7 are neutral and those of pH below 7 are considered acetic and materials with pH greater than 7 are called alkane.

This information is very important because the value of pH indicates how the materials are reacting with others to be taken into account during application.

Acid/Alkaline Balance

Feeling healthy and energized needs the body to achieve a perfect balance between alkaline and acidic foods. If we eat a modern diet, the balance in our food choices will be flipped to opposite of what our body needs. To test the body balance, the blood pH should be measured. Ideally, the blood pH is between 7.35 and 7.45 which is slightly alkaline. Keeping alkaline blood pH is crucial for healthier life, because acidic blood prevents oxygen from reaching cells, which stops cells from functioning properly and hence, the body unable to producing energy and it will drastically impair metabolic processes in the body (Waugh and Grant, 2007).

A diet containing plenty of animal proteins and deficient in vegetables and fruits may cause low-grade metabolic acidosis which has adverse health consequences, which may be especially true as we age (Hietavala *et al.*, 2015).

The acid – alkaline balance is a condition in which the ratio of carbonic acid to bicarbonate in the blood is maintained at equilibrium state. Although, the hydrogen concentrations of the blood and body fluids may be slightly altered, due to serious disturbances of metabolism or in the functioning of the body organs. All foods may be classified chemically as:

- (1) Acid forming foods (all kinds of meats, fish, shellfish, and eggs), while cereals and breadstuffs show a moderate acidity.
- (2) Alkaline/base forming foods (most of the fruits and vegetables), while milk and cream show a slight alkalinity. The citrus fruits contain acid radicals, but once metabolized in the body, it become potentially alkaline.
- (3) Neutral foods (pure fats, sugars, starches, and foods free of minerals) (Tobey, 1936).

Alkaline Diet

The alkaline diet is based on the idea that, replacing acid-forming foods and increasing alkaline-forming foods, can improve health. Proponents of this diet claim that it can help diseases like cancer (Joe, 2018). This diet can alter the pH of our body, and balanced the pH after which we notice increase in energy levels, better digestion, and easier fat loss, less pain from inflammation, better mental focus and better moods plus, a healthier and more active life (Gerry, 2012). Alkaline diet can help us lose weight and avoid problems like arthritis and cancer. The theory is that some foods, like meat, wheat, refined sugar, and processed foods, cause our body to produce acid, which is bad for us. So, according to the science behind this diet, eating specific foods that make our body alkaline can protect those conditions.

Using the revolutionary alkaline lifestyle provides an easy-to-follow diet that does not limit the food we can eat. Eating alkaline rich foods steering clear of acid-forming processed foods, creates harmony within the body, reduces the strain on the body's digestive system, boosts the immune system, increases energy, and maintaining blood sugar levels (Victoria, 2013).

Table 1 pH values of food products

<i>Foods and drinks items</i> <i>Fruits</i>	<i>~ pH level</i>	<i>Foods and drinks items</i> <i>Vegetables</i>	<i>~ pH level</i>	<i>Foods and drinks items</i> <i>Others</i>	<i>~ pH level</i>
Apples	3.85	Artichokes	5.75	Tofu (soybean curd)	7.2
Apricot	4.05	Asparagus	6.35	Lemon juice	2.3
Bananas	4.85	Avocados	6.43	Apple juice	3.68
Blue plums	3.1	Baby corn	5.2	Tomatoes, juice	4.35
Blueberries	3.2	Beans	6.1	Tomatoes, paste	4.1
Figs	5.5	Beets	5.95	Tomatoes, puree	4.39
Grapefruits	3.4	Beets	5.95	Vinegar	2.9
Grapes	3.35	Broccoli	6.6	Maple syrup	5.15
Limes	2.4	Cabbage	6.0	Jam, fruit	4.0
Mangoes, ripe	5.9	Carrots	5.95	Jellies, fruit	3.25
Melon, honey dew	6.34	Cauliflower	5.6	Ketchup	3.9
Oranges	4.0	Celery	5.85	Butter	6.25
Papaya	5.6	Radishes	5.95	Honey	3.9
peaches	3.7	Corn	6.7	Corn starch	5.5
Pears	4.0	Cucumbers	5.45	Molasses	5.25
Pineapples	3.6	Eggplant	4.9	Corn syrup	5
Pomegranates	3.1	Leeks	5.84	Sugar	5.5
Prunes	3.8	Mushrooms	6.35	Flour	6.15
Watermelon	5.39	Okra	6.1		
Olives	5.6	Onions	4.8		
Pumpkin	5.25	Potatoes	5.65		
Tomatoes	4.6	Spinach	6.15		

In the ordinary mixed diet, the acid and alkaline forming elements will be reasonably well balanced. However, a majority of alkaline foods is desirable, because normal blood is mildly alkaline, with a hydrogen ion concentration (pH) averaging 7.35 (Tobey, 1936).

Acidic Foods

We should be aware how acid and alkaline materials/foods interact with the body before deciding to avoid acidic foods and follow alkaline diet if the acidic foods are harmful to health. When foods metabolized in the body through a chemical processes, leaves behind a chemical residue known as ash. This ash can be either acid-forming or alkaline-forming, when interact with the body fluids. According to the hypothesis, foods containing acid-forming substances lower the pH level of the blood which should be balanced by alkaline materials particularly calcium leaching from the bones. So consuming acid-forming foods for quite some time increases the bone loss of calcium, thereby increasing the risk of osteoporosis. However, alkaline foods are counteracting the effect of excess acid in the body (Charlotte, 2018).

A pH of 0 indicates high level of acidity, a pH of 7 is neutral (neither acidic nor alkaline), and a pH of 14 is the most alkaline. Each type of food has some advantages and disadvantages, all depend on our diet, health, needs (children, teenagers, and pregnant women, all need proteins, vitamins, and calcium), or on our preferred test.

Foods that add high acidity to the body (pH 4.6 or lower) which must be limited or avoided include; grains, sugar, some dairy products, fish, processed foods, all types of meats, fresh and processed, sweetened beverages, and high protein foods. Too much acidity can also increase the risk for cancer, liver problems, and heart diseases. It is advisable to limit the following foods since they affect the acid-alkaline balance or the health in negative ways. These are Corn oil

- (1) Sweeteners (sugar, molasses, maple syrup, processed honey, and aspartame).
- (2) Salt.
- (3) Condiments (mayonnaise, soy sauce, and vinegar).
- (4) Hard and processed cheeses.
- (5) Grains (corn, rice, and wheat).
- (6) Coffee (Zohra and Erica, 2018).

Alkaline Water

If we want to determine the acidity or alkalinity of foods and drinks, measuring the pH values is the solution. The pH values ranges from 0 to 14. The distilled water is neutral and having a pH of 7. When minerals added to the water, it may slightly change its pH value. Any substance below pH 7 is considered acidic and that above pH 7 is considered alkaline. Alkaline water also called

Table 2 Foods' degree of acidity/alkalinity

<i>High Acid</i>	<i>Medium Acid</i>	<i>Low Acid</i>	<i>Food items</i>	<i>Low Alkaline</i>	<i>Medium Alkaline</i>	<i>High Alkaline</i>
Canned and dried fruit	Apple Mango Grapefruit Peach Orange Pear Pineapple	Green banana Plum Date Pomegranate Watermelon	Fruits	Yellow banana Avocado	Kiwi Pear Blueberry Cherry	Lemon Lime
Chocolate	Canned Vegetables	Sweet potato Cooked veg Pickles Kidney bean	Vegetables	Okra Squash Celery Lettuce Beet	Carrot Olive Tomato Corn Cabbage	Asparagus Spinach Broccoli Garlic Kale Sprouts Hemp heart
Roasted nuts	Cashew Peanut	Brazil nut Flaxseed Pecan Walnut	Nuts and seeds	Chestnut	Almond Sesame seed	
White bread Chips Pastries	Barley Oat bran	Whole grain bread	Grains	Quinoa Millet	Wild rice	
Sausage Canned; tuna, Beef Processed cheese	Chicken liver Turkey Oyster	Venison Fish	Meat			
		Yogurt	Eggs and dairy	Whey Soy milk/ chees		
Cotton seeds Palm Soft drinks Grapefruit juice Coffee	Goat cheese Goat milk Sunflower		Oils	Canola	Flaxseed coconut	Olive
	Wine Beer Liquor	Grapeseed Green tea Soy milk Rice milk Almond milk	Beverages	Ginger tea		Herbal tea
	White/brown sugar Molasses	Fructose	Sweeteners	Raw honey Raw sugar	Maple syrup Stevia	
Mustard seed	Yellow mustard White pepper	Vanilla Vinegar	Herbs and spices	Horseradish Nutmeg	Garlic powder Cayenne Fenugreek	Turmeric Basil Cumin Coriander

alkaline ionized water intake may exert positive effects on body weight improvement and cause elevation of metabolic activity. Water produced from minerals such as magnesium and calcium, has high pH level and rich with hydrogen ions. This functional water is introduced as a therapeutic strategy for health promotion, disease prevention, antidiabetic and antioxidant ([Massimiliano et al., 2016](#)).

Alkaline water typically has a pH of 8–9. However, pH alone is not enough to import substantial alkalinity to water. Alkaline water must also contain alkaline minerals and negative oxidation reduction potential (ORP). ORP is the ability of water to act as antioxidant. The more negative the ORP value, the more antioxidizing it is ([Rena and Rachel, 2018](#)).

According to research findings by Mayo Clinic, regular water is best for most people. However, alkaline water with a pH 8.8 may help deactivate pepsin, the main digestive enzyme in the stomach that causes acid reflux and it may have benefits for people who have high blood pressure, diabetes, and high cholesterol. On the other hand, the soft drinks, which are obviously acidic, have very positive ORPs leading to many health problems. Meanwhile, alkalized waters have highly negative ORPs ([Katherine, 2016](#)).

pH Values of Food Products

Table 1 shows the approximate pH values for some selected food products, in which variation exists due to growing conditions and methods of processing. The list in the table includes fruits, vegetables, juices, and other stuff ([Zohra and Erica, 2018](#)).

Acid/Alkaline Foods Chart

To rejuvenate health and make someone look or feel younger, fresher, and livelier we should focus seriously on the information provided in [Tables 1](#) and [2](#), that shows a list of some selected foods we used to eat on daily bases and apply them in our everyday life. In addition to that, one should drink plenty amount of alkaline water based on the weight. Each kilogram of body mass needs ± 300 ml of alkaline water or any other available type of water (mineral or ordinary) to ensure that the body is at its healthiest condition and the pH is at a perfect balance. We can chose our favorite foods fitted into this acid and alkaline food chart, provided that, we keep a perfect balance of acidity and alkalinity for healthy lifestyle ([Yuri, 2016](#)).

Recommendations

Numbers of recommendations, that said to help reduce certain health conditions, such as high blood pressure, heart disease, and other serious diseases. These are:

I recommend and encourage the following;

- (1) A regular pH testing of the urine or/and saliva to monitor the pH level of the body to control your diet system and achieve a green, healthy, and sustainable lifestyle.
- (2) Drinking alkaline waters with pH slightly above 7.
- (3) Mix acid and alkaline diet for normal individuals.
- (4) Alkaline diet for certain individuals with health problems.
- (5) Avoid or stop taking sugar “forever” and replace it with natural honey or stevia. Since sugar is the main food for cancer cells.
- (6) If you suspect you have problems with acidity, you can make changes to your diet system to help improve symptoms.
- (7) Remember that fruit juices are acidic too. So, you should use a straw when drinking fruit juices. This keeps the acidity of the juice from coming in direct contact with your teeth.
- (8) Drink plenty of waters. The amount of water needed every day is based on the weight. For each kilogram of weight, you need minimum of 300 ml of water, or until the color of urine is same as the color of water (colorless).
- (9) Increase alkaline foods and reduce acidic foods as much as possible to control the effects of acidity the stomach and other organs.
- (10) Keep the engineering materials away from acidity sources to avoid oxidation that may collapse the metal structures.

Heat Affected Zone Morphology of TIG Torch Welded HSLA Steel in Presence of Ti and V Microalloying Elements

Moh HA Musa, Md Abdul Maleque, and Mohammad Y Ali, International Islamic University of Malaysia, Kuala Lumpur, Malaysia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Nowadays, the high strength low alloy steels (HSLA) became indispensable alloys as these steels have unique properties, such as high strength, excellent toughness, and good weldability and can efficiently be welded by all types of fusion welding methods. It is used in different applications like the oil and gas transmission lines, manufacture of large ships, pressure vessels, offshore oil drilling platforms, building construction, bridges, and storage tanks (Ragu Nathan *et al.*, 2015). The microstructure constituent and mechanical properties of the welded joint of HSLA steel are the main factors deciding the welding quality. Characterization and evaluation of the properties of the welding areas are necessary to know their behavior as the alterations occurred after the welding process. However, these steels create a harder heat affected zone (HAZ) due to non-uniform heating and cooling in weld metal and base metal, which is susceptible to cold crack and the residual stresses formed in weldments cause detrimental in the material properties (Alipooramirabad *et al.*, 2017; Musa *et al.*, 2015; Show *et al.*, 2010). The local brittle zones (LBZs) and local hard/soft zones are often observed in HAZ. The formation of an LBZ depends on the microstructure in the coarse grain region. Brittle microstructures include large prior austenite grain size, upper bainite, and high-carbon martensite islands. This heterogeneity has remarkable effects in toughness and strength of HAZ and any degradation in the properties occurring in welding and joining of HSLA steel in-service conditions which may leads to a severe failure at an unexpected time (Han *et al.*, 2018). The existence of local brittle zones (LBZs) is one of the most important fractures controlling parameters in respect to metallurgical effects observed in HAZ. For HSLA steels the general tendency in HAZ is:

- The coarse-grained HAZ (CGHAZ) mostly deteriorates toughness.
- The constituent of Martensite-Austenite (M-A) can be large in CGHAZ.
- Microcracks initiate in M-A structures or between M-A, and the matrix structure.

Additionally, the welding process is a critical stage in the manufacturing of structural parts and the microstructure and mechanical properties of the welded joints must be appropriate in order to guarantee the durability and reliability of the components (Baptista *et al.*, 2011). Therefore, it is necessary to find a solution to this problem associated with the welding operation that greatly affects the main properties of these alloys and restrict their uses. Many efforts have been made to eliminate the welding defects concentrated in the welding areas especially HAZ, but no definite or complete solution was found from the previous research works through different heat treatment processes and post-welding heat treatment (PWHT).

The excellent mechanical strength and toughness can be achieved in HSLA steel weld metals by the formation of acicular ferrite microstructure. This can be achieved from the microalloying elements due to intermetallic compounds formed through thermal cycling at the interface between the inclusion and the matrix (Beidokhti *et al.*, 2009). The microalloying elements such as vanadium and titanium contribute extra strength through the formation of carbides and nitrides, acting directly to strengthen the steel by precipitation, or indirectly by mechanisms leading to a refinement of the ferrite grain size (Han *et al.*, 2018; Musa *et al.*, 2017). The addition of titanium to the welds changed the nature of inclusions from the Mn-base inclusions to the Ti-base ones. The precipitated titanium carbonitrides can act as beneficial hydrogen traps and delay cracking in hydrogen sulfide environments. Vanadium is used to interfere with the austenite grain growth at peak temperatures results in fine grain, therefore, achieves good toughness and strength (Beidokhti *et al.*, 2009; Li *et al.*, 2018). Therefore, the objective of this work was to study the effect of microalloying elements such as titanium (Ti) and vanadium (V) powder additions on the hardness and the morphology of the HAZ formed during TIG torch welding process of X65-HSLA steel material.

Experimental Method

The HSLA steel utilized in the present work, designated as API X-65 was imported from China in the form of plates with a chemical composition containing 0.08% C and 10 mm in thickness which was used as a substrate material for this investigation and the chemical composition of the HSLA steel is presented in Table 1.

The specimens with the dimensions of 120 mm × 50 mm × 5 mm were cut out from the plate by using CNC machine. The samples surface was rubbed off with SiC paper and degreased using acetone. The 45 μm sizes of Ti and V particles of 99.97% purity were used as preplacement for TIG torch melting and the amount was 1 mg per mm² area of the specimen surface. The Ti and V powders were first made into a pasty mass by mixing using a predetermined amount of organic PVA (polyvinyl acetate) binder, distilled water, and alcohol and then placed on the substrate surfaces (Adeleke and Maleque, 2014). The preplaced specimen was then dried in an oven at 60°C for 1 h to remove moisture. A Miller-Telwin 165 TIG torch source was used for melting purposes. The direct current electrode negative (DCEN) mode and a 3.2 mm diameter tungsten electrode were used in pure argon

Table 1 Chemical composition (wt%) of the API-X65 steel

atmosphere with a gas flow rate of 20 L/min to prevent excessive oxidation. The arc was produced using a different heat input (E) which was calculated with the formula: $E = \eta IV / (v)$, where V is the welding voltage, I is the welding current, (v) is the welding speed and η is the efficiency of heat absorption, which is given as 48% for TIG torch melting (Dieter Radaj, 1992; Easterling, 2013). The cooling time from 800°C to 500°C ($\Delta t_{8/5}$) is widely used to represent the cooling rate index during welding which was adopted in this investigation. It is approximately proportional to the net heat input and can be calculated in terms of equation ($\Delta t_{8/5} = 5 \eta E$) for the welding of HSLA steel plates (Dong *et al.*, 2014; Grong and Matlock, 1986). The melting of the preplaced powder layer was done under the torch at a constant electrode traverse speed of 1 mm/s. The optimum parameters of the TIG torch technique were generated by applying a current of 70 A to 100 A with interval 10 A, and the voltage of 25–40 V with interval 5 V (Maleque *et al.*, 2015). The preplaced specimens with powder before and after welding along with TIG torch welding setup are shown in Fig. 1.

The characterizations of melted microalloying elements addition in HSLA steel were investigated using microhardness testing machine, optical microscope equipped with a digital camera, and JSM 5600 scanning electron microscope (SEM) to characterize the microstructure and the morphology of constituent of HAZ. Microstructural characterization of the HAZ was performed in transverse cuts from the welds. Standard metallographic procedures were followed to obtain polished samples after TIG torch welding by grinding with different grades of silicon carbide papers and polishing with diamond suspensions. Specimens were etched with a solution of Nital diluted 2% to reveal the different regions of the welds and its microstructure. The microhardness was measured at a distance between measurements 200 μ m by using Wilson Wolpert Vickers microhardness tester with a 500-gf load and 10 s dwelling time using a diamond indenter to make an indentation which is measured and converted to a hardness value. An average of three readings was used.

Results & Discussion

The morphology of welding tracks with and without Ti and V powder at different heat inputs were visually inspected and their surfaces were seen to be free from any cracks or any discernible defects. These additions of microalloying elements were investigated by a variety of techniques to characterize their effects on the morphology of HAZ of X65-HSLA steel. The successful application of this steel depends on the degree of deterioration of the parent metal during welding.

The Effect of Heat Input on Hardness and the Width of HAZ

Hardness is one of the most important critical factors indicating the quality of the welding and its performance in service. From Table 2 the hardness of HAZ of welded X65 HSLA steel showed a remarkable change.

Table 2 The effect of heat input on hardness and width of welded API-X65 steel HAZ

Sample no.	Current (A)	Voltage (V)	Heat input (E) (J/mm)	Cooling rate ($\Delta t_{8/5}$) (sec)	Hardness of HAZ (Hv _{0.5})			Width of HAZ (mm)		
					Without powder	With (Ti)	With (V)	Without powder	With (Ti)	With (V)
1	70	25	840	2.02	249.3	230.2	223.5	1.37	1.28	1.26
2	80	30	1152	2.76	243.6	213.4	220.5	1.48	1.41	1.29
3	90	35	1512	3.63	218.5	214.5	225.2	1.96	1.67	1.56
4	100	40	1920	4.61	209.0	200.2	203.3	2.24	1.84	1.66

**Fig. 2** The effect of heat input on: (a) Hardness of HAZ and (b) Width of HAZ of welded X-65 HSLA steel.

In general, the hardness values of the HAZ region decrease with the increase in heat input. Under the low heat input condition (heat input of 480 J/mm); the hardness value in the HAZ is higher than that in the base metal (The hardness of the as-received base metal is 165 HV). The highest hardness value (249.30 HV) achieved in the CGHAZ where the heat input was lower, due to the formation of lath martensite largely in the CGHAZ. The CGHAZ is considered as the local brittle zone in HAZ.

Both Ti and V microalloying elements additions to the welding region exhibited a decrease in hardness of HAZ with an increase in heat input during welding in this HSLA steel as shown in Fig. 2(a). The hardness of modified welding samples varies from 230.20 HV to 200.23 HV and from 225.25 HV to 203.32 HV for Ti and V samples respectively. These variations attributed to the formation of hard phase and grains of the welded sample. Although the minimum hardness values are in the range of 200.23–203.32 HV, for both Ti and V added HAZ samples but they do not vary significantly, rather closer to the value of the base metal taking into account that all hardness values are within the scope of the acceptance criterion of HAZ and base metal.

The effect of heat input on the hardness lies in the influence of heat input on the microstructure in HAZ. Fig. 2(a) shows that the lower welding heat input which corresponds the higher cooling rate leads to the formation of martensite and increases the microhardness of the HAZ and weld as shown in Fig. 3. Also, as the welding heat input increased, the cooling rate became slower and martensite disappeared gradually with the formation of bainite. So the average hardness of HAZ was decreased from 249.30 HV to 209 HV with the increase of welding heat input, due to the microstructure transformation from martensite to bainite (Dong *et al.*, 2014).

The width of HAZ as shown in Table 2 was influenced by the welding parameters, the wider HAZ width is undesirable and it does not provide any benefit to the welding joint. When different welding heat inputs were used, the HSLA steel base metal near the fusion line experienced different thermal cycles, and different microstructures were formed in HAZ (Wang *et al.*, 2012). When the welding heat input was only 480 J/mm, the cooling time ($\Delta t_{8/5}$) was about 2.02 s, and this fast cooling rate easily produced brittle and hard phases in HAZ. The width of the HAZ and its components greatly increases from 1.37 to 2.24 mm with increasing heat input from 480 J/mm to 1920 J/mm when the cooling rate was about 4.61 s. However, when the microalloying elements Ti and V were added to the welding samples of this steel, the width of HAZ reduced remarkably. The width of HAZ at lower heat input (480 J/mm) decreased by 0.9 mm and 0.11 mm for the modified welded samples with Ti and V respectively as shown in Fig. 2(b). Whereas, at higher heat input (1920 J/mm) the reduction in width of HAZ of modified welded samples were 0.4 mm and 0.6 mm respectively. As shown in Fig. 2(b), both elements have a significant influence on the shape and the width of HAZ with a slight variation between them. The two V and Ti promote carbonitride (C, N) precipitation hardening. They have the ability to limit austenite grain growth due to the undissolved V-Ti (C, N) during the thermal cycle welding (Guillal *et al.*, 2018). This gives rise to grain refinement and limits the coarsening of M-A brittle phase, during intercritical reheating. The minimizing of the risks and failures resulting from the critical welding area especially in HAZ is the main function of these additions.

Fig. 4 SEM micrographs of welded X-65 HSLA steel showing: macrostructure of welding zones of modified samples with (a) Ti and (b) V; and microstructure of HAZ of modified samples with (c) Ti and (d) V.

The Effect of Heat Input on the Microstructure of HAZ

After welding the HSLA steel, the HAZ microstructure in the vicinity of the boundary of the welded joint is coarse-grained with the formation of martensite and bainite and, consequently, the hardness exceeds the hardness of the parent metal (Pirinen *et al.*, 2016). The microstructure of welded steels processed at a relatively higher cooling rate contained pearlite and acicular ferrite in addition to the primary ferrite-pearlite constituents. However, at the lower cooling rate, it reveals a microstructure composed of martensite, bainite, pearlite and polygonal ferrite. Fig. 3 reveals that the microstructures of base metal and the heat affected zones of welded HSLA steel. It can be seen that the micro structure of HSLA steel base metal is typically composed of predominantly polygonal ferrite (white) and pearlite which consisted of carbides (black).

While the microstructure of HAZ was typical martensite structure having obvious lath martensite boundary (M), lath bainite (B), retained austenite (RA), and various ferrites (F) with different morphologies could be observed in HAZ of HSLA steel joints (Lan *et al.*, 2012). The mechanical properties and microstructure of the weld metal (WM) and heat affected zone (HAZ) deteriorates due to the increase of welding heat input which increases the peak temperature and decreases the cooling rate. Moreover, the higher heat input promotes austenite grain coarsening and the formation of a higher fraction of large and thin shaped

martensite-austenite (M–A) constituents in the CGHAZ, which leads to properties deterioration (Musa *et al.*, 2018). Practically, it is not always acceptable to increase the welding heat input to increase productivity. Fig. 4 shows the macro and microstructure of the modified welded X-65 HSLA steel samples with titanium and vanadium microalloying elements.

When the microalloying elements of Ti and V were added to the welding tracks, the welding pool and HAZ microstructures were changed due to the effect of these elements as shown in Fig. 4(a) and (b). Melted Ti in welded HSLA steel, usually refines the microstructure by forming stable Ti-rich particles Ti(C, N) as shown in Fig. 4(c). These increased Ti inclusions leads to an increased number of nucleation sites for AF, and performs alteration in the microstructure from allotriomorphic ferrite to acicular ferrite (AF), and refines ferrite grain size (Han *et al.*, 2018). Additionally, a fine and homogeneous distribution of Ti-rich carbonitrides precipitates Ti(C, N) can constrict austenite grain coarsening during austenitization and contribute to grain size refinement when austenite transforms at low temperature. The titanium may precipitate nitrides (TiN) to prevent the grain growth during austenitizing at high temperature (Fletcher *et al.*, 2011; Yan *et al.*, 2006), and it may also precipitate carbonitrides Ti(C, N) or carbides in deformed austenite to retard the recrystallization and growth of austenite during cooling, which is beneficial to grain refinement and enhances the strength of steels greatly (Xia *et al.*, 2017).

The effect of vanadium microalloying addition on the transformation of HAZ microstructures was observed. The microstructure of HAZ of modified HSLA samples with V powder in Fig. 4(d) revealed that the grains became smaller than the grains of normal welded samples. This is due to the addition of these microelements which improves structural and mechanical properties of the welded zones. It can be said that vanadium micro addition plays a very important role in the refinement of ferrite, by enhancing ferrite grain boundary nucleation at early transformation stages and intragranular nucleation later on (Hernandez *et al.*, 2005).

The above mentioned results confirm that microalloying with vanadium and titanium significantly slows down the austenite to ferrite transformation. This is beneficial for pinning of austenite grains and since longer time is available, it enhances ferrite nucleation at prior austenite grain boundaries mainly by V(C, N) or Ti(C, N) precipitates and particles.

Conclusion

In this paper, the effect of microalloying additives (Ti & V) on HAZ of X-65 HSLA steel after TIG torch welding was investigated. It was found that these enhanced the hardness and the microstructure properties of HAZ of high strength low alloy steels. The decrease in the hardness of the HAZ was observed before and after the addition of the two elements with increasing heat input. The discrepancy between the hardness reading after the addition of Ti and V was attributed to the position of the indentation, the grain size and the phases formed.

When the microalloying elements of Ti and V were added to the welding samples of this steel, the width of HAZ reduced remarkably which provided thinner HAZ layer and overall better quality of welding. Both elements have a significant influence on the shape and the width of HAZ with a slight variation between them. Their effects are reflected in minimizing the risks resulting from the critical welding area (HAZ).

On the other hand, the addition of these microalloying elements during the welding process led to the formation of carbonitrides of Ti and V(C, N) in the form of precipitations during the thermal cycle welding. These gave rise to pinning of austenite grains and enhance ferrite nucleation at prior austenite grain boundaries, resulting in a grain refinement and limiting the coarsening of M–A brittle phase in HAZ.

Introduction

Hybrid material sourced from nature has existed for billions of years. Nature developed hybrid organic–inorganic materials with exceptional fracture resistance and structural capabilities with complex design (Wegst *et al.*, 2015). Examples of hybrid organic–inorganic materials in nature include bone and narge. Hybrid materials are defined as the combination of organic and inorganic materials, where the range of the hybrid composite is from a few nanometers to tens of nanometers (Mammeri *et al.*, 2005). The organic and inorganic materials result in different properties. The combination of the organic and inorganic components in the formation of hybrid materials is limitless (Kickelbick, 2007). Thus, a new combination can lead to a new type of hybrid materials.

The organic materials are recyclable, cheaper, sustainable, and easy to process (Liu, 2014). Meanwhile, the inorganic materials are excellent in terms of dielectric constant, thermal stability, and high charge mobility (Krasia-Christoforou, 2015). Examples of natural organic–inorganic materials are mollusc shells, crustaceans, and bone, including human bones (Zhu and Yuan, 2015). Manmade hybrid materials have been produced since ancient times. The discovery of Maya blue, which is an intercalated organic pigment in clay minerals, proves the use of hybrid material in the past (Gómez-Romero and Sanchez, 2005). Maya blue is unique due to its resistance to solvent and aging, as well as acid.

Nevertheless, the rapid development of hybrid materials for scientific and industrial purposes has taken place since the early 1940s (Zhu and Yuan, 2015), as shown in Fig. 1. In the 1950s, the intercalation of organic units inside clay and inorganic lamellar compounds was discovered. The term “hybrid composite” was only coined in the mid-1980s. The hybrid materials become a hot topic in the 1990s. From 1980 to 1995, the sol–gel chemistry was established to produce products with different structure, morphologies, and physical properties.

Hybrid materials are defined as the mixture of two moieties on the molecular scale (Saravanan *et al.*, 2018; Tanasa and Zanoaga, 2012). Besides, hybrid materials are often referred to as the component that is formed via in situ process. Based on the International Union of Pure and Applied Chemistry, hybrid materials are defined as the materials made up of the mixture of inorganic components, organic components, or the combination of both. Organic material offers structural flexibility, convenient processing, semiconducting potential, tunable electronic properties, photoconductivity, and efficient luminescence (Haddad and Lichtenhan, 1996; Noh *et al.*, 2013). On the other hand, the inorganic material provides magnetic and electric properties, as well as thermal and mechanical stability (Arkenbout, 2010; Polyakov *et al.*, 2011). The combination to form hybrid material does not take place in normal conditions, but it occurs on the nanometric scale. The resulting hybrid material acquires new properties, which are determined by chemical and individual components, structure, and interface of the different components (Gu *et al.*, 2017). Therefore, hybrid materials offer many possibilities in terms of properties because they can be created by altering the individual components, volumetric content, morphology, size, and arrangement (Ashby, 2005).

Fig. 1 Rapid development of hybrid materials from the early 1940s to 2016.

The hybrid material systems are divided into homogeneous and heterogeneous systems. The detailed explanation of hybrids material is described via the possible molecular interaction between organic and inorganic species (Mir *et al.*, 2018). In general, hybrid materials are classified into two categories, namely class I and class II, as follows:

- Class I refers to the weaker interactions consisting of van der Waals and hydrogen bonding.
- Class II refers to strong molecular interactions such as covalent, ionic, ionocovalent, and coordinative bonding.

To date, hybrid materials provide many opportunities and challenges, so that the development of hybrid materials is still ongoing. Therefore, this review will cover hybrid material development in terms of development history, synthesis, and properties of hybrid materials.

Synthetization Methods of Hybrid Material

Fundamentals

In this context, hybrid materials are defined as the combination of organic and inorganic materials. The advantage of hybrid materials is that they can combine the different properties of organic and inorganic components. The range of the hybrid composite is from a few nanometers to tens of nanometers (Mammeri *et al.*, 2005). According to the Materials Science Society of Japan (1993), hybrid materials are categorized into four sections: Composite, nanocomposite, hybrid, and nanohybrid. Fig. 2 shows the hybrid material classification is based on the size range.

Organic components can extend the range of matrices available for synthetic chemistry. Organic materials can help in modifying mechanical properties, thus enabling the production of films and fibers, by the casting of various geometric structures for integrated optics to control the network porosity and connectivity and adjust the hydrophilic–hydrophobic balance. Organic components also contribute to physical or chemical properties including electrical or optical characteristics, electrochemical behavior, and chemical or biochemical reactivity. There are two approaches in the hybrid material preparation (Tanasa and Zanoaga, 2012):

- (1) The preformed building blocks react with each other to form a final hybrid material where the precursors maintain their original integrity;
- (2) One or two structural units are formed from the precursors that are transformed into a network structure.

The hybrid materials are prepared using methods as follows (Gómez-Romero and Sanchez, 2005):

- Copolymerization of functional organosilanes, macromonomers, and metal alkoxides
- The encapsulation of organic components within sol–gel derived silica or metallic oxides
- The organic functionalization of nanofillers, nanoclays, or other lamellar structure compounds

Materials

The materials often used to produce hybrid materials are polymers and metals. Polymer helps to integrate the benefit of both materials. The metal component provides the rigidity while the polymer keeps the metal shape intact and offers many functions, besides having damping characteristic. The advantages of polymer and metal are summarized in Table 1, while Table 2 tabulated the properties of hybrid material organic (polymer) and inorganic (transition metal oxides) components.

Processing Methods

To achieve a balance of organic and inorganic between properties, there are many approaches in the combination of organic and inorganic materials. This includes blending process, sol–gel method, emulsion polymerization and photopolymerization, electrocrystallization, hydrothermal wet chemistry and coordination approaches, intercalation, microwave-assisted and electrochemical synthesis, as well as block copolymer-mediated synthesis (Krasia-Christoforou, 2015). Each approach has its own advantages and disadvantages. Table 3 summarizes the advantages and disadvantages of each hybrid material preparation approach.

Properties of Hybrid Materials

Hybrid materials demonstrate better properties than their individual counterparts, where the inorganic components play a role to enhance the mechanical and thermal stability, modulate the refractive index (RI or *n*), provide an accessible and interconnected porous network for sensing or catalysis, or contribute magnetic, electronic, redox, electrochemical, or chemical properties (Azadmanjiri *et al.*, 2018).

There are different combinations of organic and inorganic components in hybrid materials. The hybrid material properties vary, depending on the material (organic/inorganic), structure, and different component interface. As shown in Table 4, the optimum combination can enhance mechanical strength and thermosensitivity, improve thermal and chemical stability, and regulate optical, anticorrosive, magnetic, electrical, and thermal properties as well as fire retardancy. The hybrid material properties were characterized through UV-visible spectroscopy, scanning electron microscopy, and transmission electron microscopy (Ogoshi and Chujo, 2005).

Physical Properties of Hybrid Materials

The hybrid of organic–inorganic materials often has porous crystalline structure (Loy and Shea, 1995). The porous structure contributes to adsorbent properties. Most of the hybrid materials also have unique structure, making them an excellent catalyst for chemical reactions. Besides, hybrid materials have exceptional optical property. Often, they have passive optical properties that do not change by environmental excitation, or active optical properties such as photochromic and electrochromic materials (Kickelbick, 2007).

Mechanical Properties of Hybrid Materials

To predict the mechanical properties of hybrid materials is still a challenge in materials science (Gon *et al.*, 2017). Nevertheless, hybrid materials have exceptional fracture resistance and structural capabilities through extrinsic toughening that protects any

Table 3 Advantages and disadvantages of the hybrid material synthetization methods

<i>Synthetization method</i>	<i>Definition</i>	<i>Advantages</i>	<i>Disadvantages</i>	<i>Refs.</i>
Building block approach	Partially keep their molecular integrity throughout the material formation	The building blocks can be designed in such a way to give the best performance in the material formation	N/A	Kickelbick (2007)
In situ formation	Contrary to the building block approach the in situ formation of the hybrid materials is based on the chemical transformation of the precursors used throughout materials' preparation	Simple, commercially available molecules are applied and the internal structure of the final material is determined by the composition of these precursors but also by the reaction conditions	N/A	Kickelbick (2007)
The sol-gel process	Wet-chemical technique which is to disperse the materials (discrete, colloidal) in a liquid to bring it back in a solid form	- The most applied method - Produce an excellent homogeneity due to the mixing at high molecular level - Required less energy consumption as no need to reach the melting temperature	- Difficult to avoid the residual porosity and oh group - Preferential precipitation of a particular oxide during the sol formation - High initial cost	Ogoshi and Chujo (2005)
In situ approach	Contrary to the building block approach the in situ formation of the hybrid materials is based on the chemical transformation of the precursors used throughout material preparation	Provides stabilization to the metal nanoparticles by the organic soft material and advantageously precludes the use of external reducing or capping agents in many instances	N/A	Ehtisham <i>et al.</i> (2016), Divya <i>et al.</i> (2016)
Electrocrystallization	Process that occurs at the electrode/solution interface that leads to the formation of a solid phase at the electrode surface	- Produces large, good-quality single crystals - The reaction selectivity, the product formation, the phase purity, the kinetics of reaction and the nice crystal growth	- It requires the need of high-purity starting materials in contrast to other techniques - The formation of the product is affected by several parameters like, current, potential, solvent, supporting electrolyte, and also by the operating temperature	Zhang <i>et al.</i> (2014)
Hydrothermal method	Includes the various crystallizing techniques from high-temperature aqueous solution at high vapor pressures (T above 100°C and p above 1 atm)	- Simplicity, it lost cost, it energy saving, it better nucleation control - Pollution-free	- This technique needs expensive autoclaves, and a longer reaction time - Reproducibility is poor, especially when aiming to achieve identical crystal	Finn and Zubietta (2001)
Wet chemistry approach	Variety of simple or classical techniques that involve direct experimentation with liquids	- Simple and inexpensive starting materials, almost no damage occurs during the process; quite easy manipulation - Less time consuming	Poorly controllable especially with small amount of starting materials	Azadmanjiri <i>et al.</i> (2018)

Table 4 The properties of hybrid materials

<i>Organic</i>	<i>Inorganic</i>	<i>Condition</i>	<i>Key properties</i>	<i>Refs.</i>
Chitosan	Tetraethoxysilane/ vinyltriethoxysilane	N/A	Improve tensile and elongation with better thermostability and thermal decomposition	Kickelbick (2007)
Polymerized poly (methyl methacrylate)	Zinc oxide	Polymerization	Flexible design, high transparency, Ion barrier performance	Demir <i>et al.</i> (2006)
	Titanium oxide	Polymerization	Flexible design of particle size and photocatalytic activity	Ling <i>et al.</i> (2006)
Carbon nanotube	Polyaniline	In situ emulsion polymerization	Increase conductivity properties	Deng <i>et al.</i> (2002)

crack from the applied loads (Wegst *et al.*, 2015). The mechanical properties of hybrid materials are influenced by the ratio of organic and inorganic composition. Imbalance in the ratio will affect the viscous–elastic behavior or elastic–plastic characteristic. Besides that, the properties of the hybrid material also depend on the interface between organic and inorganic materials (Munch *et al.*, 2008).

The tensile or compression test is conducted to determine the elastic properties of the hybrid materials. The high content of the inorganic composition, typically more than 15% is good for elastic modulus (Gon *et al.*, 2017). This is because the hybrid materials become more brittle once filler increases. However, when the inorganic composition is less than 15%, there is no change in the elastic behavior. The inorganic component causes the material to become brittle due to high porosity.

Besides, high inorganic content in hybrid materials affects fracture toughness. The composition and size of the inorganic materials determine the hybrid material mechanical behavior. In fact, fracture toughness is influenced by the type of inorganic components, which often consist of metal oxides of Si, Ti, Zn, and Al. Another mechanical property is hardness, which is determined from indentation test. Hardness is associated with wear resistance. The hardness of hybrid materials is influenced by the component morphology during the synthesis.

Optical Properties

The inorganic–organic composites are also versatile in terms of their optical properties. Researchers are actively investigating the optical properties of the hybrid composite to achieve the following objectives (Munch *et al.*, 2008; Lebeau *et al.*, 1999):

- (1) Adjustability of RI over a wide range
- (2) Light transmittance over a wide range
- (3) Lighter weight compared with the inorganic optical materials
- (4) Better heat resistance and stability compared with the organic materials
- (5) Better flexibility compared with the inorganic optical materials

Based on the previous literature (Mahmood and Azarian, 2017), the outstanding optical properties of the inorganic–organic materials have been addressed by researchers. Unlike other composite materials, the inorganic–organic hybrid materials possess a high degree of transparency due to the dispersion of the different components on the material and the smaller structural unit compared with the wavelength of light (Kickelbick, 2014). As reported in one study performed by Mahmood and Azarian (2017) the hybrid composite of epoxidized natural rubber/zirconia (ENR-50/zirconia) demonstrated excellent optical transparency in the visible light range. The transparency of the hybrid materials was influenced by particles. At the high particle concentration level, the particle agglomeration triggered increased light scattering, which induced lower transparency and higher turbidity. On the other hand, the density of the particles strongly influenced the light scattered within the hybrid materials.

The optical properties of hybrid material are often characterized through the RI. Currently, the development of the high refractive hybrid composite is rapidly ongoing due to motivation to achieve perfect balance with mechanical properties and thermal properties RI is defined as the ratio between the velocity of light in a vacuum to its velocity in a specified medium. Normally the organic materials have a RI in a range of 1.3–1.7; meanwhile the inorganic material can have RI below 1 or 3 (Kim and Park, 2016). Through a combination between organic and inorganic materials, the different RI can be modified based on the desired application. The RI of the materials can be relatee molar volume (V_m) and polarizability d to $\text{th}(\alpha)$ of the materials. As shown in the previous research work (Lü and Yang, 2009), the hybrid materials can be tuned to different RI through implementing different heat treatment, type of metal alkoxides, and the weight or volume fraction of inorganic content. Table 5 shows the summary of the RI of the hybrid inorganic–organic materials.

Hybrid Material Applications

The combination of organic and inorganic components has the potential to replace the traditional materials. The development of hybrid material synthetic methods has improved their mechanical properties on the macroscopic scale. Nowadays, researchers focus on hybrid materials with advanced mechanical properties for transportation industry, such as vehicle structure (Gutfleisch *et al.*, 2011; Darder *et al.*, 2007). The process technology and modular construction of hybrid materials highlight their strengths in several applications. Due to the improvement in terms of mechanical and physical properties, hybrid materials are used for many applications such as coating, nanocomposite, medicinal, optical, and electronic domains, which will be discussed later.

Coating Applications

Surface coating is crucial to protect products against environmental and harsh conditions such as multiple loading, corrosion, and abrasion. The coating components in general are mixed into coating formulation, which is applied to a substrate. There are two commonly used coatings methods, namely liquid coating and powder coating. The liquid coating is made based on organic solvent, water, or both, in which solvents are used to dissolve the organic components, control viscosity as required, and control the film formation (Grosso, 2011). Meanwhile, there are two types of powder coating, thermosets and thermoplastics, which are

Table 5 The summary of the refractive index (RI or *n*) of the hybrid inorganic–organic materials

Type of materials	Thickness (μm)	RI	Wavelength (nm)	Refs.
ENR	150	1.472	–	Mahmood and Azarian (2017)
ENR-10% zirconia		1.482

	Polyester	Alkyd	Acrylic	Acrylic
	Polyurethane	Polyurethane	Vinyl ether	Phenolic
	Alkyd	Styrene-Butadiene	Bismaleimide	Epoxide/polyester hybrid

Note: KICKELBICK, G., 2007. Introduction to hybrid materials. Hybrid Materials: Synthesis, Characterization, Applications. John Wiley & Sons, 1–46.

used with common polymers such as polyurethane, polyester-epoxy (hybrid material), epoxy, and acrylics. In terms of hybrid coating, both thermosetting and thermoplastic systems are used (Clemens and Clemens, 2005). Interestingly, the most common functional group is ester, which is in the form of drying oils, alkyds, vinyl acetate, polyesters, and acrylics (Jones *et al.*, 2017). The most common organic binders are polyurethanes, acrylics, and alkyds. Polymeric binders are used in multiple media such as water and organic solvents. The types of media for liquid coating and powder coating are described in Table 6.

In recent decades, organic and inorganic coatings have gained attention as the new functional material (Zareba-Grodz *et al.*, 2004). In general, hybrid material is formed through hydrolysis and condensation of modified silicates with conventional alkoxide precursor (Williams *et al.*, 2001). The characteristics of hybrid coating may lead to complaints in the future regarding its effectiveness to protect any surfaces from natural conditions, as demonstrated by Kachurina *et al.* (2002) on the corrosion resistance performance of multilayer ormosil/conversion coating on 2024-T3 aluminum alloys. Besides, Chou *et al.* (2003) investigated the corrosion resistance behavior of sol–gel derived thin films deposited on stainless material using potentiodynamic polarization curve analysis. Researchers have explored the use of silane-based treatment to protect aluminum (Kachurina *et al.*, 2002; Chou *et al.*, 2003), aluminum alloys (van Ooij, 1998), iron (Subramanian and van Ooij, 1998), and steel (Sundararajan and van Ooij, 2000) from corrosion. In addition, the application of hybrid coating with wood antibacterial properties (Donath *et al.*, 2004), as well as fire, chemical, physical, and water resistance (Wang *et al.*, 2011; Trepte and Böttcher, 2000) was investigated. There is also interest in hybrid coating with embedded metal oxide nanoparticles to protect wooden products from fiber, humidity, and sunlight (Wang *et al.*, 2011). Table 7 summarizes the coating application of hybrid materials, including its method, material, equipment, and purpose.

Nanocomposite Development

Nanocomposites are a new class of composites that are prepared by mixing the inorganic particles into melt polymer at the nanometer stage. The types of nanocomposites depend on the dimension of the dispersed particles in nanometer range. The first type is characterized by one dimension, which is present in the form of nanometer sheets with hundreds to thousands nanometer long. The second type is characterized by two dimensions in the nanometer scale; for instance, carbon nanotubes (Jorio *et al.*, 2007), cellulose whiskers (Oksman *et al.*, 2006). The third type is in three dimensions, which involve isodimensional nanoparticles such as spherical silica nanoparticles (Yang *et al.*, 2004). Nanocomposites have at least one dimension in nanometer scale, which is in the range of 1–100 nm. Moreover, the nanocomposites of conducting polymers and inorganic particles are used to prepare electroactive materials (Cómez-Romero *et al.*, 2003). For example, a polythiophene composite and platinum particles

Table 7 The summary of the coating application technique of hybrid materials

<i>Technique</i>	<i>Materials</i>	<i>Equipment</i>	<i>Purpose</i>	<i>Refs.</i>
Dip coating	Vinyl acetic acid/zirconium n-propoxide	Environmental scanning electron microscopy	Wood protection	Girardi <i>et al.</i> (2014)
In situ	Polyurethanefattyamide/silica	IRPrestige-21, IRAffinity-1, FTIR-8400S, Optical microscopy	Corrosion protection	Ahmad <i>et al.</i> (2012)
Sol-gel process	Polyesters/tetraethoxysilane	Fourier transform infrared spectroscopy (FTIR), thermal gravimetric analysis, TENCOR-P10 Surface Profiler	Protective coating	Frings <i>et al.</i> (1998)
In situ	Polyvinyl chloride/ZnO	FTIR, X-ray diffraction patterns, field emission scanning electron microscopy and transmission electron microscopy	Corrosion resistance	Olad and Nosrati (2013)
Sol-gel process	Polyfunctional sol-gel precursor/oligomers	UV irradiation, QUV-A irradiation	Outdoor application	Liu <i>et al.</i> (2005), Hofacker <i>et al.</i> (2002)

<i>Materials</i>	<i>Key properties</i>	<i>Application</i>	<i>Refs.</i>
The core integrity of inorganic nanobuilding blocks	Vectorial chemistry, hybrid networks, chemical strategies	Nanoparticles	Sanchez <i>et al.</i> (2001)
Polymer-layered silicate nanocomposites	High thermal stability, gas barrier properties, and good flame retardancy	Future application	Alexandre and Dubois (2000)
Plant oil/clay nanocomposites	Flexible property	Renewable resources	Uyama <i>et al.</i> (2003)
Polyaniline/organoclay nanocomposite and EPDM rubber	High conductivity, good mechanical properties	Antistatic coating/ electromagnetic shielding	Soto-Oviedo <i>et al.</i> (2006)
The molecular hybrids PAni/H ₄ SiW ₁₂ O ₄₀	Better energy-storage performance	Solid-state electrochemical capacitor cells	Cuentas-Gallegos <i>et al.</i> (2005)

Abbreviation: EPDM: ethylene propylene diene monomers.

are used as the oxygen-reducing electrode in the fuel cell application (Bashyam and Zelenay, 2011). Table 8 presents the applications of nanocomposite hybrid material.

Medical Applications

In recent years, hybrid materials have gained attention in the research of biomaterials, which focus on hybrid material medical applications, that involve inherent degradability, cytotoxicity, and biocompatibility (Yu *et al.*, 2010; Jiang *et al.*, 2015). Vallet-Regí *et al.* (2011) demonstrated that the incorporation of osteostain peptide into SBA-16 materials reduces tissue encapsulation, which significantly improves local bone induction and develops potential formulation for clinical applications. Fig. 3 shows the schematic representation of organic-inorganic hybrid materials in biomaterials science. In addition, an excellent alternative that leads to higher control of silica leaching under in vitro physiological conditions was reported, by using different methods such as the incorporation of heteroatom into silica framework (García *et al.*, 2009).

Therefore, hybrid materials are significant in the production of bioceramics, which are utilized in medical applications. For example, stimuli-responsive drug delivery system is used as the local carrier, which is synthesized using charged ionic interaction between carboxylic-modified mesoporous silica and polyelectrolyte solution (Yang *et al.*, 2005). Also, hybrid materials are useful in cell targeting. Rosenholm *et al.* (2008) have investigated the use of mesoporous silica nanoparticles functionalized with hyperbranched poly(wedges) in cell targeting, either to assist in drug delivery or cancer cell imaging. Moreover, implant material is compatible in terms of mechanical properties and biological properties, to be applied to damaged or wounded organs. It is adequate to depend on fundamental of biomaterials and hybrids of biomedical applications. Table 9 shows some hybrid material medical applications, including the materials, key properties, and future application.

Optical Applications

Due to high transparency and mechanical flexibility of inorganic/organic hybrid materials, they have potential in optical applications. The development of synthetic strategies at the atomic and nanometer scale with enhanced properties is required. Materials for optoelectronic devices need higher thermal stability and better compatibility, to be used in semiconductor devices. The transparent

Table 10 A summary of hybrid material optical applications

Materials	Key properties	Application	Refs.
Hybrid semiconductor nanomaterials	Optical properties and functionalities	Energy conversion, sensing, electronics, photonics, and biomedicine	Li and Zhang (2009)
A covalently bonded gold nanoparticle/polylysine (AuNP-PLL)	Reverse saturable absorption, free-carrier absorption, electromagnetic interaction	Miniaturized electronic devices, catalysis, sensors, data storage	Sun <i>et al.</i> (2005)
Inorganic/organic hybrid polymer with silicate-based	High transparency, solvent less, high curability, high thermal stability	Versatile application	Nawata (2013)
Oleic acid-modified LaF_3/Er , Yb nanocrystals	Excellent dispersibility, strong emission	Amplification application	Wang <i>et al.</i> (2007)
Porphyrin and fullerene covalently functionalized graphene hybrid material	Enhance nonlinear optical response	Photonic and optoelectronic devices	Liu <i>et al.</i> (2009)

inorganic glasses and organic polymers have improved over the years. The physical and chemical properties of hybrid material can be functionalized according to its use, such as in waveguides and microoptical devices (Houbertz *et al.*, 2003). The example of hybrid material optical applications are waveguide materials (Zhang and Fallahi, 2005), photodetectors (Wang *et al.*, 2010), and nonlinear optical materials (Innocenzi and Lebeau, 2005). Hybrid materials also have potential in the making of LEDs and photovoltaics, in which the market for the products is large (Kim *et al.*, 2010). Table 10 summarizes the hybrid material optical applications.

Table 11 A summary of electronic applications of hybrid material

Materials	Key properties	Application	Refs.
CuInSe ₂ nanocrystals	High sensitivity and stability	Photodetectors	Wang <i>et al.</i> (2010)
Graphene/free-standing nanofibrillar PEDOT/P (VDF-HFP) nanohybrid	Improved contact surface, high sensitivity, piezo-resistivity	Sensitive electronic skin application	Park and Jang (2015)
Transition metal oxide/polymer	Excellent electrochemical and thermal stability, high electrocatalytic activity	Electrocatalytic application	Rajesh <i>et al.</i> (2005)
Zinc oxide nanoparticle /polystyrene	High stability, high conductivity	Electronic application	Verbakel <i>et al.</i> (2006)
Nanocrystalline zinc oxide nanoparticle (nc-ZnO)/regioregular poly (P3HT)	High solar-energy conversion efficiency	Solar energy application	Beek <i>et al.</i> (2006)

Electronic Applications

There use of hybrid materials in electronics industry has increased, due to the development in integrated circuit performance. Hybrid materials are installed in electronic devices, which are resistant to high temperature using without compromising the device performance. Electrochemically active hybrid materials have several advantages. For instance, hybrid materials offer stability like solid materials but possess liquid properties at the same time. Hybrid materials can integrate the electrical conductivity of solid materials and ionic conductivity of liquid materials, which is useful for electronic devices that provide low-k dielectrics (Liu *et al.*, 2001). The silicon-derived hybrid material is significant in electronic devices (Hartmann-Thompson, 2011). Table 11 presents several electronic applications of hybrid material.

Conclusion

Hybrid materials have served many purposes in the advancement of modern technologies. Even though many studies were performed on hybrid materials, the reported properties and characteristics are still insufficient. This is because hybrid material properties and behavior are influenced by synthetic methods, so that even a small alteration can make a difference. However, the issues in hybrid material synthesis must be solved so that many parties can leverage the hybrid material technology. To refine the production of hybrid materials, further studies should be conducted to improve the physical and mechanical properties. The research in regard to hybrid materials should be carried out to overcome the obstacles in various applications. Yet, the effect of high inorganic composition in the different environmental conditions (such as temperature) remains the same.

Due to the hybrid materials' modular composition, many components are now suitable to be involved in hybrid material organic/inorganic combination. Therefore, there is no limit in the future applications.

Introduction

The interface reaction during processing of SiC_p/6061Al composite play a major role in determining the mechanical properties and performance in service (Maleque *et al.*, 2017). Aluminium matrix composite (AMC) possesses potential for the development of lightweight materials where efficiency and improved performance is needed (Adebisi *et al.*, 2014; Wang *et al.*, 2018). Moreover, the mechanical properties is strongly influenced by the microstructure of the processed aluminium composite considering the interface reaction between the matrix and reinforcement phase. The nature of phases present is dependent on the chemistry and interface mechanism which controls the efficiency of load transfer between the matrix and reinforcement (Adebisi *et al.*, 2016a,b). Aluminium composite can be processed using various techniques which include both liquid (centrifugal, squeeze, stir casting) and solid state (powder metallurgy, diffusion bonding) conditions (Narasimha *et al.*, 2013). The stir casting process is commonly employed due to its simple and cost effective advantage. With this technique, there is possibility of a strong interfacial reaction to take place between the matrix and reinforcement phase owing to the prolonged contact during processing. Studies have shown that Al alloy reinforced with various carbide such as SiC, TiC, B₄C or graphite either in form of fiber or particulates results in the formation of Al₄C₃ (alumina carbide) at the interface as presented in the equation:

This formation of Al₄C₃ is detrimental to the development of aluminium composite and also degrades the mechanical properties of the composite (Liu *et al.*, 2015). The degree and extent to the resultant interface reaction depends on a variety of factors which include, processing technique, matrix phase alloying elements, nature of surface treatment and thermal treatment on the composite. In order to limit Al₄C₃ formation during liquid state processing of SiC_p/6061Al composite, three main methods may be adopted;

- (1) Modification of the matrix alloy by addition of Si to the aluminium matrix in order to hinder the interface reaction.
- (2) Pre-oxidation/surface treatment of the reinforcement phase.
- (3) Optimization of process parameters in order to control and limit the extent of interfacial reaction.

Studies conducted by through theoretical calculations (Lee *et al.*, 1998), quantitative modeling (Wang *et al.*, 2015) and experimental data (Sozhamannan and Prabu, 2010) have estimated the equilibrium Si content required to prevent the formation of Al₄C₃ considering the variations in Al and Si as well as other compounds present. Moreover, determining the optimum process condition such as stirring speed, time (Adebisi *et al.*, 2016a,b) and process conditions (Adebisi *et al.*, 2017, 2016a,b; Sozhamannan *et al.*, 2012) has also shown considerable tendency in limiting the formation of Al₄C₃. Besides, the surface modification technique incorporates different procedure which has been experimented by researchers (Lee *et al.*, 2000; Urena *et al.*, 2004).

However, this study aims to investigate the interface nature and reaction products considering the oxidation treatment of the SiC_p reinforcement at high temperature on SiC_p/Al6061 composite. The interface study was characterized using the scanning electron microscope (SEM) and X-ray diffraction (XRD) facilities.

Experimental Procedure

Oxidation Treatment of SiC Particle

The reinforcement used in this study is SiC_p with an average size of 40 μm. The SiC_p is prepared through oxidation treatment in a miniature particle preheating furnace attached to the aluminium stir casting furnace with a heating capacity of 1500°C as shown in Fig. 1. Oxidation treatment of the SiC_p improves the casting processability by means of chemical interface control. The oxidation of the SiC_p is carried out at 1200°C for 2 h in order to initiate surface oxidation. This process is expected to catalyze the formation of SiO₂ layer on the surface of the SiC_p. Moreover, the layer thickness increases with temperature and time to a certain range (Kim and Lee, 2006).

Composite Processing

In this study, AA6061 aluminium alloy is used as the matrix material and silicon carbide particles (SiC_p) as the reinforcement phase material. Table 1 shows the properties of the matrix and reinforcement materials.

Fig. 1 Bottom pouring stir casting furnace (Swamp Equip, India).

Table 1 Properties of matrix (AA6061) and reinforcing (SiC_p) phase

Property	Unit	Al (6061)	SiC _p
Density	g/cm ³	2.7	3.22
Melting point	°C	660	2973
Coefficient of thermal expansion	μm/m°C	23.4	4
Thermal conductivity	W/m K	166	126
Young's modulus	GPa	70	410

Note: Veeresh, K.G., Rao, C., Selvaraj, N., 2012. Studies on mechanical and dry sliding wear of Al6061–SiC composites. *Composites Part B: Engineering* 43 (3), 1185–1191.

The composite was developed using an electric resistance induction stir casting set up incorporated with a preheating furnace, vacuum chamber, stainless steel stirrer and attached die cavity as shown in [Fig. 1](#). The melting furnace for Al alloy matrix has a heating capacity of 1000°C. The temperature value is determined with a K-type thermocouple for sensing the temperature during the melting process until the desired temperature is attained on the indicator. After melting of the aluminium alloy, dross formation is extracted from the melt surface with a coated skimmer which has been preheated. Moreover, before the incorporation of the prepared (oxidation treated) SiC_p, 1 wt% magnesium was added in the aluminium melt to improve the wettability between the matrix and reinforcement phase. Subsequently, the injection of treated SiC_p was slowly added to the aluminium melt within an average of one (1) min as the stirrer (stainless steel) is gradually lowered into the furnace in order to perform stirring and pouring. The die steel is heated to 500°C for 1 h and then positioned in a vacuum chamber of 350 mmHg before pouring take place. Throughout this process, the composite melt is monitored to be in a molten state.

Metallography and Microstructural Preparation

The surface of the developed SiC_p/6061Al composite is prepared using the ASTM Standard E8-11 ([ASTM E3-11, 2017](#)) as a guide. The grinding is conducted using a four station hand grinder with various stages of Presi abrasive papers ranging from P240 to P1000 (coarse to fine size). Each of the grinding stage removes the scratches from the previous coarse paper and this is achieved by orienting the sample perpendicular to the previous scratch position. Between each grade, the SiC_p/6061Al composite is washed thoroughly to prevent contamination from the previous grinding surface. All through the process, wet grinding is applied to avoid possible side effects due to heating. The grinder also incorporates a flushing action for loose particles to flow from the grinding surface.

The polishing process is conducted using Presi Mecapol P260 machine with a Ø200 mm adhesive polishing cloth on the wheel disc. The polishing cloth has an abrasive size of less than 1 μm and an alumina micropolisher of 0.3 μm is used with a rotation rate of 150–200 rpm. Moderate polishing pressure is applied on the composite as the disc is rotating and this process takes about 3–5 min.

Fig. 2 SEM micrographs of SiC_p: (a) As received-untreated (b) oxidized at 1200°C showing a relatively smooth surface of the oxide layer.

The composite is washed thoroughly with warm soapy water; followed by alcohol to prevent contamination. Finally, minimum polishing pressure is applied and within a short period a mirror like and free from scratches is achieved.

In order to obtain a clear and satisfactory surface examination a proper metallography procedure is required. This process minimizes the number of irregularities on the prepared SiC_p/6061Al composite surface. Chemical etching is achieved through the use of Keller's agent, in order to ensure that all phases present are clearly identified when viewed under the microscope. JEOL, JSM 5600 scanning electron microscope (SEM) is used to characterize the layer formation on the SiC_p and also the morphologies of the interfacial reaction products. Phase identification is conducted with Shimadzu 600 XRD diffractometer.

Results and Discussion

Effect of Oxidation Treatment on SiC_p

The silicon carbide particle (SiC_p) is heat treated to 1200°C for 2 h before incorporation into the aluminium melt. Particle pre heating removes impurities on the SiC_p surface and also alters the surface composition due to formation of silicon dioxide (SiO₂) layer. Observations on the surface morphologies of the as received and heat treated (oxidized) SiC_p were conducted using the scanning electron microscope (SEM). **Fig. 2(a)** and **(b)** show the micrographs of the as received and oxidized SiC_p respectively.

The oxidized SiC_p shows a relatively smooth surface due to the uniform formation of the silica layer. The layer formation is visible at the edges of the SiC_p with a whitish blurred surface which indicates the presence of the silica layer as indicated with the arrows on the high magnification view in **Fig. 2(b)**. Moreover, the SiO₂ also serves as a source of Si which is used to suppress and prohibit the formation of Al₄C₃ (Kim and Lee, 2006).

The phase analysis in **Fig. 3** shows the SiC particle surface experiences the formation of SiO₂ layer when compared to the as received SiC_p. The phases show the presence of SiO₂ diffraction peaks at 2θ for 28.4°, 33.5°, 38° and 41.2°.

Interfacial Reaction Products of Al-SiC_p Composite

The exposure of SiC_p to high temperature environment mainly above 900°C, influences the weight gain on the particles due to reaction with oxygen which forms a thin layer of SiO₂ on the surface of SiC as shown in **Fig. 4**. The oxidation of SiC_p at elevated temperature removes contaminants, impurities, and absorbs moisture from the particle surface. This helps to form a clean and uniform protective layer of SiO₂ as shown in **Figs. 3** and **4**.

The reaction taking place during the oxidation process is effective in prohibiting a direct contact between the SiC_p and Al matrix alloy due to the formation of SiO₂. This process proceeds according to the following reactions in **Eqs. (1)–(3)**:

In spite of which reaction that may proceed, one mole of SiC will oxidize completely into one mole of SiO₂ as presented in the equations. SiO₂ is purposely introduced as a form of surface coating on SiC_p to enhance the wetting property between the SiC_p and the Al, and to serve as a barrier to limit SiC_p from being attacked by molten Al so that the reaction in **Eq. (4)** is restricted (Kindl *et al.*, 1992):

When the reaction of aluminium and oxidized SiC_p occur, the contact gives rise to interface reactions. These reactions takes place considering the Al alloy, SiC_p, SiO₂ and Mg present. In order to examine the morphology of the interfacial reaction products on the oxidized

Fig. 3 XRD phase analysis of SiC_p: (a) As received and (b) oxidized at 1200°C for 2 h.

Fig. 4 SEM micrograph of oxidized SiC_p with thin layer formation of SiO₂.

surface of the SiC_p after reacting with aluminium melt, the SiC_p from as cast composite is evaluated and the SEM micrograph is shown in Fig. 5. Though, the Al 6061 alloy has Mg as one of the constituent element, but an additional 1 wt% Mg is added in order to enhance the reactive wettability. This element produces reaction products with SiO₂ layer on the SiC_p surface during composite processing. When Al is alloyed with Mg and Si as constituent elements, Mg₂Si (magnesium silicide) precipitates by the reaction in Eq. (5) (Shi *et al.*, 2001):

In addition, there is a possibility of Mg attacking the SiO₂ directly to form Mg₂Si according to the following reaction in Eq. (6):

The formation of MgAl₂O₄ was found in presence of Mg and SiO₂ (Shi *et al.*, 2001; Ren *et al.*, 2008) as shown in Eq. (7) and also presented in Figs. 5 and 6.

In this present study, there is no evidence of reaction in Eqs. (5) and (6), because Mg₂Si have not been detected as shown in the XRD phase analysis in Fig. 6. Since the contact reaction of Al with SiO₂ film layer is much higher than that of Mg in Al, Al reacts with SiO₂ as shown in Eq. (8). Thus, the formation of MgAl₂O₄ is more acceptable to take place base on reactions in equations 4.9 to 4.10 as presented;

Fig. 5 SEM micrographs showing the growth of MgAl₂O₄ in Al-SiC_p.

Fig. 6 XRD phase analysis of Al-SiC_p without alumina carbide formation.

The free energy of formation per mole of O₂, of MgO is the lowest, followed by that of Al₂O₃ and SiO₂ (Shi *et al.*, 2001). The change in free energy due to reaction in Eq. (10) is also negative (Shi *et al.*, 2001), which implies that MgO and Al₂O₃ react to form MgAl₂O₄. The mechanism of improvement in wettability on alloying of Al with Mg in the Al-SiC_p composites, involves the reduction of surface tension of molten Al by removal or modification of the oxide skin as suggested by earlier authors (Rohatgi *et al.*, 1986; Cappleman *et al.*, 1985). The presence of the MgO and MgAl₂O₄ phases at the interfaces creates a diffusion barrier which inhibits and restricts the formation of Al₄C₃ due to the reaction of Al and SiC_p as shown in the XRD phase analysis in Fig. 6.

Conclusions

The following conclusions were achieved from this study;

- (1) The successful formation of SiO₂ layer was achieved as a result of oxidizing the reinforcement phase (SiC_p) for a period of 2 h at 1200°C.
- (2) The successful use of reinforcement coating (SiO₂) through oxidation of SiC_p and addition of 1 wt% Mg to influence the formation of stable catalyst compound known as MgAl₂O₄ to enhance the interfacial bond strength and improve wettability between the Al alloy melt and SiC_p.
- (3) The reaction product shows that the presence of Mg at the reactive boundary of the interface coupled with the formation of SiO₂ on the surface of SiC_p confirms the presence of MgAl₂O₄ and MgO due to the reaction synthesis between Al alloy and SiC_p.
- (4) The combination of MgO and MgAl₂O₄ phases at the interfaces creates a diffusion barrier which inhibits and restricts the reaction between Al and SiC_p to form Al₄C₃.

Life Cycle Assessment in Buildings: An Overview of Methodological Approach

Grace KC Ding, University of Technology, Sydney, Australia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Buildings impact significantly on the environment and the construction of buildings consume approximately 50% of raw materials, 71% of electricity, 16% of water usage and produce 40% of waste disposed of to the landfills (Oduyemi *et al.*, 2017). In addition buildings are responsible for emissions and wastes of 18% and 50% respectively caused by raw material exploitation and building operation (Kibert, 2016). Building is a complex product that has a long lifespan. Buildings play an important role in maintaining the well-being of the humankind and the environment which has escalated due to the emergent of building-related health issues.

Buildings offer the most significant potential for mitigating environmental impacts and much attention has been given to improving their efficiency and performance (Hong *et al.*, 2015; Giesekam *et al.*, 2016). Operating efficiency has been the main focus of studies as this is the stage that most of the energy is consumed and most of the wastes are generated in a building's lifecycle. With the advancement of technologies and shifting to the use of renewable energy in the improvement of operating efficiency, more attention has now been given to the upstream flows of energy and emissions embodied in materials (de Wolf *et al.*, 2016).

Life cycle assessment (LCA) is a well-developed tool to assess the environmental performance of materials, products, systems or even the whole building through quantifying the resource consumption and waste generation from the upstream flow of raw material extraction, manufacture, transport, construction and use, and the downstream flow of end-of-life (EOL) deconstruction and disposal (Ding, 2014). The LCA study allows the impact of discrete systems and materials to be weighted against each other so that environmentally friendly materials can be produced and used for the design and construction of buildings. The use of LCA to assess the environmental performance of materials and buildings has increased dramatically over the last decades.

The main objectives of the chapter are to overview the methodological approach of LCA and its uses in the construction industry. This chapter begins with an overview of the LCA methodology, its definition and the International Standards Organization framework, followed by the types and models. This chapter also presents the structure of an LCA approach in the assessment of buildings in the four lifecycle phases of product, construction, use and EOL, and followed by an examination of LCA studies of materials and buildings from the literature. The chapter concludes with a discussion on the limitations of LCA studies in materials and buildings.

An Overview of LCA

The Development

The concept of LCA was originated in 1969 when the Midwest Research Institute in the US conducted the very first LCA study for the Coca-Cola to compare the differences between using plastic and glass bottles (Baumann and Tillman, 2004; De Benedetto and Klemeš, 2008). The reasons for the development of LCA were the problems with rising waste accumulation and the acknowledgment of limited resources and energy supply issues (Klopffer and Grahl, 2014). LCA received more attention from the beginning of the 1990s due to the accelerated deterioration of the environment (Baumann and Tillman, 2004). LCA was initially used for assessing performance impact of a particular product on the environment but it has now expanded to include the assessment of government policy and incorporated as part of the product design process (Kohler and Moffatt, 2003).

LCA is a systematic framework that focuses on dealing with the inflows and outflows and offers a methodology for assessing the environmental impacts spanning from the extraction of raw materials to the eventual disposal (Klopffer, 2006). Lei *et al.* (2003) describe LCA as a quantitative method used to assess the environmental burdens of particular products. Kohler *et al.* (2010) further describe the use of LCA is a paradigm shift in the evaluation of products and services in buildings.

The principal functions of LCA are therefore included quantifying and evaluating the environmental performance of products, processes or systems so that decision-makers can optimize their selections among alternatives. Additionally, it helps to identify potential improvements that can be made to lessening the overall impacts at specific stages in a lifecycle perspective (Wei *et al.*, 2008; Ahn *et al.*, 2010). All the processes of a particular product or service that compose a product system make up its lifecycle and can, therefore, be compared to other product systems that perform an equivalent function.

The Overview

LCA is well regarded as a useful and important assessment tool to sustain manufacturers, suppliers, consumers, policy-makers, and building stakeholders in making decisions about the environmental performance of products and buildings (Jeswani *et al.*, 2010). The Society of Environmental Toxicology and Chemistry (SETAC) has defined LCA as a quantitative method used to assess the

environmental burdens of particular products, processes or systems over their entire lifecycle (Klöpper, 2006; Chau *et al.*, 2015). According to Taygun and Balanli (2007), the use of LCA aims at assisting in:

- Conserving natural resources.
- Preventing environmental pollution.
- Supporting environmental parity.
- Preserving diverse sustainable ecosystems.
- Developing environmental legislation.
- Developing environmental execution evaluation in environmental management systems.
- Providing the manufacture of environmentally friendly building products.
- Decreasing the environmental impacts and health risks in building operation and maintenance.

In the building sector, the improved environmental performance of buildings is the main driving force for saving resources and reducing emissions. An environmental assessment is the evaluation of the environmental effects and from that, possible reduced impacts to the environment may be identified and developed. LCA is used to calculate the quantities of resources demanded and waste produced per functional unit (Rebitzer *et al.*, 2004). LCA has now been extensively used in the building industry in four main areas of evaluating manufacturing processes, developing product labels, comparing materials and methods, and analyzing whole buildings (Simonen, 2014).

International Standards Organization (ISO)

In the early 1990s, there were concerns over LCA results being inappropriately used and claimed by product manufacturers with regards to the environmental benefits of their products for marketing purposes (Curran, 2008). In addition, there were pressures from environmental organizations to standardize the LCA methodology and guidelines on an international level. SETAC initiated to develop a definition for LCA and developed a standardized methodology for LCA studies which has led to the development of the ISO 14040 series (Ekvall, 2002; Curran, 2008).

The standardized methodology for LCA studies was first published by the International Standards Organization (ISO) as part of the ISO 14040 series in 1997. ISO 14040 series provides a standardized method of tracking, reporting, compiling and evaluating inputs, outputs and the potential environmental impacts of a product, process or system throughout the lifecycle. (ISO, 2006a,b). The introduction of these international standards was seen as a milestone for LCA practice, although they are not entirely suited to every methodological choice in LCA. However, Ekvall (2002) states that even though the introduction of the ISO 14040 series was a huge milestone for LCA, the guidelines and principles as outlined in the standards are not in unison with every methodological choice in LCA. As the standard is a generic framework, it allows analysts to use the standards and produce virtually any LCA results. Ekvall (2002) goes on to state that since LCA methodology is continuously evolving, the content of the standard becomes outdated relatively quickly. Therefore for the international standards for LCA to be useful, it is imperative that the standards be updated by the ISO to encompass new ideas that are continually incorporated into the guidelines as state-of-the-art development.

Since the initial release of the ISO 14040 series, it was revised in 2006 (ISO, 2006a,b). The LCA framework has been developed through the ISO 14040 series to include:

- ISO 14040 - Environmental Management: Life Cycle Assessment - Principles and Framework.
- ISO 14041 - Environmental Management: Life Cycle Assessment - Goal and Scope Definition and Inventory Analysis.
- ISO 14042 - Environmental Management: Life Cycle Assessment - Life Cycle Impact Assessment.
- ISO 14043 - Environmental Management: Life Cycle Assessment - Life Cycle Interpretation.
- ISO 14044 - Environment Management: Life Cycle Assessment - Requirements and Guidelines.

ISO 14040 and 14044 have been internationally adopted for more regional specific standards/guidelines to facilitate a more transparent communication for improving the environmental performance of building and to enhance sustainable practices in the construction industry. The regional specific standards/guidelines include the development of the EN 15804 and 15978 standards by the CEN TC 350 in Europe to provide a methodological framework and definition of stages. Similar in the UK, the PAS 2050 was developed in 2008 to provide guidelines for the assessment of lifecycle GHG emissions of products. Internationally, the development of the GHG Protocol Product Standard in 2011 provides requirements for measuring, managing and reporting on GHG emissions (Simonen, 2014; Soust-Verdaguer *et al.*, 2016).

LCA Framework and Methodology

LCA Framework

Early studies of LCA were carried out by specialists for private companies at the discretion of individual practices to suit their own needs (Baumann and Tillman, 2004). With the standardization of the LCA methodology, the ISO has considered as a clear framework that LCA practitioners can follow when conducting an LCA study (Finkbeiner, 2014). In according to the ISO 14040 series the principal objectives of LCA are:

- To measure and appraise the environmental impact of products, processes or systems.
- To support decision making of environmentally friendly products, processes or systems.
- To identify potential improvements to improve the performance of products, processes or systems which may lead to the modification or redesigning to reduce the overall environmental impacts.

The ISO 14040 series outline that the LCA framework includes four phases of goal and scope definition, inventory analysis, lifecycle impact assessment, and interpretation as presented in Table 1. Therefore it is principally essential to define the goal and scope of performing an LCA carefully at the very beginning.

When the LCA framework is applied to undertake environmental impact analysis of buildings it can be done in the following scopes and as presented in Fig. 1:

- Individual building materials or products, e.g., cement, concrete, vinyl flooring.
- Individual building elements, e.g., substructure, reinforced concrete external walls.
- One or several stages in a building lifecycle, e.g., building material production stage, construction on-site, operating phase.
- Whole building analysis, e.g., full lifecycle study.

The arrows in Fig. 1 indicate the interaction within and between the phases that are required to ensure that goals, scope, methods and results are consistent, complete and relevant. The results of an LCA study varies depending on the goal and scope set

Table 1 The purposes of the four phases of LCA

LCA phase	Purposes
Goal and scope	• Identifying the purpose of the study, the limits and the boundary • Setting up a functional unit for the study • Identifying key processes, material and energy flows for analysis
Inventory analysis	• Collecting data • Analyzing material and energy flow for each stage of the lifecycle • Disassembling the process that constitutes at different stages of the lifecycle • Collecting, quantifying and calculating data of inputs and outputs of the system for the entire lifecycle
Life cycle impact assessment	• Quantifying the demand for resources • Evaluating the likelihood of environmental impacts • Classifying and characterizing inventory data into various impact categories using either midpoint or endpoint approaches
Interpretation	• Interpreting environmental impacts results • Conducting improvement analysis for potential opportunities to reduce impacts • Recommending either system improvements or environmentally preferable product and process selection

Table 2 Strengths and weaknesses of LCA study

Strengths	Weaknesses
● Provides quantifiable metrics for evaluating environmental impacts ● Results can be used to compare various alternatives or to identify the optimum option ● Impacts can be tracked throughout the supply chain and throughout the lifecycle to provide a more holistic understanding of the environmental impacts of products, processes or systems ● Enable manufacturers and consumers to understand opportunities for improvement and identify where trade-offs occur during the lifecycle ● Minimize the use of unsubstantiated environmental claims such as greener, low impact and so forth	● Require significant resources and time to conduct a detailed study ● Social and economic impacts of sustainability are not included in LCA studies ● Data unavailable for some specific locations and processes being studied ● Much LCA data is proprietary and may only accessible via LCA software ● A full cradle-to-grave LCA study requires the development of scenarios to outline the use and EOL phases which is highly uncertain and actual events such as natural disasters, refurbishments of buildings are difficult to model ● Assume accuracy is a significant flaw in LCA studies as results are often reported as the aggregation of industry average data without in-depth consideration of the variability and uncertainty

at the beginning. The accuracy of an LCA study may be jeopardized by the accessibility and availability of relevant data and data quality. Therefore it is important to note that the results generated in an LCA study may be considered as ongoing activities and may contribute to being part of the further study.

LCA study is important in the construction industry as it provides a systematic assessment of impacts by documenting procedures, data sources, boundaries and assumptions to ensure information clarity and facilitate greater comparability of products, processes or systems in buildings. LCA is regarded as a comprehensive methodology for impact assessment but its results may not be easily interpreted if results are overly aggregated. Transparency of processes is important for the validity of an LCA. However, this may discourage many from participating because of the concern over proprietary information. **Table 2** presents the strengths and weaknesses of the LCA study in the construction industry.

Even with the weaknesses and criticisms discussed, LCA study is still important in assisting the construction industry to enhance the goal of sustainability in construction in terms of creating and maintaining a healthy building environment, minimizing consumption of resources, reducing the generation of wastes and emissions to the surrounding environment (Ahn *et al.*, 2010).

Types of LCA

Attributional LCA

Attributional LCA is an approach used to examine the environmental flows to and from a products lifecycle within a chosen system of the functional unit (Finnveden *et al.*, 2009; Simonen, 2014). Attributional LCA specifies information with regards to the impacts of the processes used to produce and dispose of a product (Brander *et al.*, 2008). Brander *et al.* (2008) continue to state that to a large extent attributional LCA methodology was the basis for the formation of the international standard for LCA.

Attributional LCA studies in most cases develop quantitative relationships between input and output within a product. These quantitative relationships allow precise and accurate results to be produced based on the assumption that there will be no impact on the overall changes to the technologically modified environment within the chosen system. Outcomes from the attributional LCA can also be used to compare the direct impacts of different products (Simonen, 2014). Furthermore results from attributional LCA can be used to recognize opportunities for reducing direct impacts at various stages in the product lifecycle. However attributional LCA does not consider any indirect effects within the system boundary. Therefore even though this system boundary issue may be considered as a limitation, but in turn, it denotes that the system boundary of each product in the study will not overlap. It implies that the issue of double counting will not happen as in theory each of the processes of the product merely is added together with the total resulting in the total environmental emissions for the products (Brander *et al.*, 2008).

Consequential LCA

Consequential LCA attempts to model future consequences of changes in the output of a product (Finnveden *et al.*, 2009; Simonen, 2014). It considers effects both inside and outside the product lifecycle. Consequential LCA also models casual relationships that stem from the decision to change the output of a particular product (Brander *et al.*, 2008).

The main difference between attributional and consequential LCA is that attributional LCA focuses on the environmental impacts associated with a product during its lifecycle; whereas consequential LCA focuses on outlining the effects of any changes, i.e., output levels of the lifecycle. According to Ekvall (2002), there are concerns with completeness in the consequential LCA where the full consequences of changes in a lifecycle can never be fully understood and assessed. This is because as the future cannot be easily envisaged, it is not possible to accurately explain the future consequences of changes. Furthermore, as LCAs are principally prone to include large data gaps, adequately forecasting future consequences of changes is very difficult to do accurately. Additionally, there are also concerns about the actual relevance of performing consequential LCAs. Ekvall (2002) states that

decision makers are more concerned with understanding the actual environmental burdens associated with products, processes or systems, than in the knowledge of what potential effects occur as a result of changes in a lifecycle.

LCA Models

There are different LCA models available depending on the type of product, product system and stages of a product's lifecycle. Some LCA models investigate a single product; some are used to investigate the relationships associated with a particular product, process or system; and others are used to compare different products. The main methods used are process-based and input-output models to account for the environmental impact of goods and services and are the foundation for the hybridized methods (Majeau-Bettez *et al.*, 2011).

Process-based model

The process-based LCA analysis method is seen as a conventional approach to LCA (Rowley *et al.*, 2009). It is aimed at the manufacturing process of a product, where all the inputs and outputs for a particular product are itemized. The two main process-based approaches are process flow diagrams and matrix representation of a product (Suh and Huppes, 2005). The process-based method is commonly referred to in the USA as the SETAC-EPA approach due to the large efforts towards its continual development by SETAC and the Environmental Protection Authority (EPA). It is a bottom-up technique that consists of reviewing the required resources and the generation of pollutants from the production processes.

The analysis first determines a system boundary or scope for the study in according to the ISO 14040. Typically this is done by a repetitive process, where an initial system boundary is chosen and then refinements are made through the introduction of new unit processes. This method can also require high resources and labour, making it quite an expensive process due to the large volume of process-specific primary data.

Input-output (IO) model

The input-output (IO) approach was designed to incorporate the economy-wide interdependencies. Wassily Leontief initially developed it in the early 1940s (Rowley *et al.*, 2009). It was not until the 1970s that Leontief proposed using the IO approach to analyzing environmental impacts. Applications of IO analysis started being used in LCA analysis in the early 1990s (Suh and Huppes, 2005). The IO model was developed as an alternative to the process-based model to overcome the limitations of boundary definition and circularity effects that are typically associated with the process-based model. In a process-based analysis, truncation errors continually occurred, because it was not feasible to collect process specific data for the entire economy (Suh and Huppes, 2005). A full system is required to quantify truncation errors and IO analysis has been adopted and used extensively as a method to indirectly estimate the levels of truncated errors that occurred as a result of the process-based LCA analysis (Majeau-Bettez *et al.*, 2011).

The IO analysis is a top-down technique that deals with the economy-wide interdependencies of industries in the national economy through the utilization of sectorial monetary transactions data (Majeau-Bettez *et al.*, 2011). It is essential to account for the movements within the entire supply chain for both direct and indirect activities during the manufacturing of a particular product.

Hybrid models

The hybrid LCA approach has been developed to combine the strengths of process-based and IO analysis into a single model. It is through the amalgamation of these two models into a hybrid model that the limitations associated with these models can be addressed and overcome (Lenzen, 2002). The three main hybrid models are tiered hybrid analysis, IO-based analysis and integrated hybrid analysis (Suh and Nakamura, 2007). IO analysis is a relatively fast approach where the upstream system boundary is most completed, whereas the process-based model, on the other hand, is more accurate to analyze the direct and downstream requirements such as construction, use, maintenance and the EOL of a product.

Advantages and disadvantages of LCA models

The process-based and IO models have both strengths and weaknesses. The development of the hybrid model is more useful for LCI data compilation and it draws on the main advantages of the process-based and IO models (Rowley *et al.*, 2009). It is through the process of linking the process-based and IO models together that hybrid model can draw on the strengths of these two methods. This, in turn, can produce more accurate results and reliability in LCA studies as a whole (Suh and Huppes, 2005). Table 3 summarizes the advantages and disadvantages of the LCA models that are commonly used in the study of environmental impacts.

LCA Studies by Life Cycle Phases of Buildings

A construction project may have various level of environmental impacts at different stages of a building's lifecycle (Malia *et al.*, 2013). Kaatz *et al.* (2006) suggest that a better understanding of building phases and their related activities is fundamental to incorporate sustainability across the different lifecycle stages of a project. Thomson *et al.* (2011) state that the project lifecycle represents an important context as it reflects the consecutive and interlinked stages of the object under consideration. The factors impacting on the sustainability performance of a building may vary according to the project type, scale, location and process. Therefore, when

Table 3 Summary of advantages and disadvantages of LCA models

Models	Advantages	Disadvantages
Process-based	- Can methodically analyze material and energy flows at every stage of the lifecycle - Comparison between products can be made easily - Weaknesses during the manufacturing process can be determined to allow process improvements for future product development assessments - It is also seen as being a more specific approach in comparison to the IO analysis	- Difficult to develop a scope for the study. Large boundary requires substantial collecting and processing of input and output data which is time-consuming and costly. For a small boundary, the environmental impacts throughout the products lifecycle may be jeopardized as various inputs and outputs out of the scope would be failed to account for - The large volume of process-specific data to be collected and analyzed may lead to the study being too expensive and time-consuming to conduct
IO	- It can overcome and address the issues related to system boundary determination and truncation errors in the process-based model - It enables fast screening of LCA of a complex system - It enables the leverage of existing economic data (e.g., annual reports) - It includes comprehensive supply chain inputs beyond what is practical for most process-based model - Publicly available data, reproducible economy-wide results, system and boundary is defined as the entire economy	- Unable to conduct comparative analysis within a sector as data is aggregated by industry - Economic data may be outdated as IO tables are usually published with a time delay for a few years - It is assumed that imported products have the same environmental impacts for products produced locally which may result in large variations in the analysis - The IO tables and databases in different nations may be different due to varying levels of completeness - Maybe more applicable for material production phase but less useful for the cradle-to-grave study - There is a high level of aggregation of products in the IO tables which may make them unsuitable for LCAs - Difficult to identify process improvements, uncertainty and product use.
Hybrid	- Suitable for more extensive and more complex studies. - To address and overcome weaknesses in the process-based and IO models in LCA studies	- The model may require time for collecting a large volume of primary data for the analysis which may turn out to be not all are significant - Requires careful selection between up/downstream to prevent double counting - The interaction between processes is hard to distinguish

sustainability performance of a construction project is examined, project stages and major activities in each stage must be specified first, so that factors influencing the project's characteristics of each stage can be identified.

Stage divisions of a building's lifecycle have been the focus of some research studies (Thomson *et al.*, 2011; Wu *et al.*, 2012). It is generally summarized that a building lifecycle consists of the extraction and production of raw materials, transportation, construction, operation and final deconstruction at the end of the lifecycle (Wu *et al.*, 2012). Even though different studies can have different goal and scope but lifecycle stages are required to be standardized. An internationally accepted and standardized building lifecycle is presented in the EN 15978 Standard (CEN, 2011). According to the EN 15978 the building lifecycle is divided into four phases as detailed and presented in Fig. 2:

- Product (A1–3) – Raw material supply, transport and manufacturing.
- Construction process (A4–5) – Transport, construction and installation.
- Use (B1–7) – Products in use, maintenance, repair, replacement and refurbishment.
- EOL (C1–4) – Deconstruction/demolition, transport, waste processing, and disposal.

As presented in Fig. 2 the common types of system boundary in LCA or partial LCA include cradle-to-gate, gate-to-gate, cradle-to-grave and cradle-to-cradle. Cradle-to-gate (A1–3) is from the stage of extraction to product completion (excluding distribution) while gate-to-gate (A3) includes only one section of the manufacturing process. The cradle-to-grave (A1–C4) includes the whole lifespan of material from extraction through use and disposal, and cradle-to-cradle involves all the processes from extraction to EOL of a product with the addition of recycling (Puettmann and Wilson, 2005; Mitchell and McFallen, 2008).

Over the years research studies were undertaken to assess the environmental impacts at the various stages of a building's lifecycle. Tables 4 and 5 extract some of the research studies on total energy consumption and global warming potential (GWP) of buildings at various stages in a building's lifecycle in according to the EN 15978 Standard. From the tables most of the LCA studies were breakdown by building stages, except the studies by Zhang *et al.* (2014) and Bawden and Williams (2015) focusing on the total impact only, the study by Serrano and Alvarez (2016) include only part of the use phase and EOL was basically excluded in the study.

The total lifecycle energy consumption in Table 4 demonstrates that the use phase (B1–6) consumes the most energy and followed by the product, construction and EOL. Both the construction and EOL phases consume the least amount of energy in a lifecycle perspective. The total energy consumption of both residential and office buildings in Table 4 varies a great deal. The variations may be due to different system boundary, material manufacturing methods, fuel consumption and so forth.

Fig. 2 Building lifecycle and system boundary. Sources: Adapted from ISO, 2006a. ISO 14040: Environmental Management – Life Cycle Assessment – Principles and Framework. Geneva: International Standards Organization. ISO, 2006b. ISO 14044: Environmental Management – Life Cycle Assessment – Requirements and Guidelines. Geneva: International Standards Organization. CEN, 2011. Sustainability of Construction Works – Assessment of Environmental Performance of Buildings – Calculation Method. UK: British Standard Institute.

Similarly, GWP is another impact category that LCA studies are considered. From [Table 5](#) the GWP generated from buildings demonstrates that the use phase generates most of the total GWP and followed by the product, EOL and construction. The GWP of both construction and EOL phases are minimal compared to the other two phases but the EOL phase has a slightly higher impact than the construction phase in the GWP.

Product (A1–3)

This is the first stage of a building's lifecycle and it involves the production of materials that are used in the construction of buildings. There are environmental impacts embedded in the production of the materials used in buildings. [Alcorn \(2003\)](#) states that energy has long been one of the most appropriate indicators of environmental impacts, in particular embodied energy as it denotes the total upstream energy consumption in materials for the construction of buildings. The energy and emissions embodied in materials include extracting raw material from the ground, transporting raw materials to factories and producing building materials. Therefore selecting the appropriate building materials based on the embodied energy and emissions content is crucial for improving the efficiency of buildings.

The energy embodied in building materials is initial embodied energy and in a typical building it ranges from 10% to 60% of the total energy use ([Ramesh et al., 2010](#); [Gustavsson and Joelsson, 2010](#)). The amount of energy and emissions embodied in the production of building materials or components is highly dependent on the type of fuel sources such as oil, diesel, electricity used in the extraction, manufacturing process and the associated quantities involved. ([Chau et al., 2012](#)).

The inventory analysis at this stage involves obtaining data for building materials from the bills of quantities if available. Otherwise, material quantities are estimated from construction drawings or field measurement of work on-site. Therefore it is important to determine the type and quantity of materials used for the building. [Table 4](#) indicates that the energy consumption (MJ/m^2) at the product phase of both residential and office buildings represents around 6%–12% of the total energy consumption. Similarly, the GWP ($\text{kgCO}_2\text{-e}/\text{m}^2$) generation in [Table 5](#) at the product phase is approximately 5%–12% of the total lifecycle emissions.

Construction Process (A4–5)

The construction phase of a building refers to a series of construction activities which include the erection of the structure and installation of building materials or components until buildings are completed. The time taken to construct a building varies according to the size and complexity of the project. A large number of machinery and site personnel are required for the

completion of construction projects. The construction stage examines resource consumption, emissions and other environmental impacts about the transportation and construction activities on-site.

The energy and emissions embodied in the construction phase include the use of equipment and transportation of materials and equipment to the site, as well as any supporting processes used on-site. Construction phase contributes a low level of environmental impact compared with the operating stage. Ortiz *et al.* (2009a) state that the construction activities account for approximately 8%–20% of energy consumption in a building's lifecycle but relatively more than the LCA studies in Table 4. The environmental impacts at this stage are relatively small compare to the operating stage of the lifecycle. However, the excessive consumption of energy and generation of emissions during site operation are negative impacts on the environment and the effect is immediate and more intensive due to the shorter period of construction compared with the operating stage (Zhang *et al.*, 2013; Huisingh *et al.*, 2015). In addition construction activities may result in other impacts such contaminating soil, surface and underground water; generating construction and demolition waste; releasing hazardous emissions and odours that may impact on the well-being of the natural and manmade environment (Gangoelle *et al.*, 2009; Ding, 2018).

The transportation of materials to the construction site has some inherent environmental impacts, namely the energy consumption and CO₂ emissions associated with the mode of transportation such as trucks, rails, ships or planes. John *et al.* (2009) state that the contribution of transport of materials to the total lifecycle environmental impacts is approximately 0.3% and 0.5%

respectively for primary energy use and CO₂ emissions which is similar to the LCA studies in Table 5. The use of locally manufactured materials reduces the overall environmental impacts but may not be as significant as the other stages. Transportation data is estimated from the average distances travel from factories or distribution centres to the construction site. Therefore the emission impacts vary with the type and mix of fuel source used in transportation as well as the operation of machinery, equipment and distance from the site.

The quantities at this stage are estimated either from bills of quantities or measurement on-site. The estimation of quantities of materials, components or systems at this phase is important as it relates to the type of machinery and equipment used for construction. The quantity of wastage due to offcuts, mishandling, mistakes in drawings and so forth are also needed to be included in the assessment (Ding, 2018). However, even though the impact may be minimal compared with the operating phase it is still necessary to include in the assessment of environmental impact as part the LCA framework to gain a holistic view of the lifecycle impacts.

In Table 4 the total energy consumption in the construction phase ranges from 1 to 22 MJ/m², representing less than 2% of the total energy consumption. Similarly, the GWP in Table 5 is less than 2 kgCO_{2-e}/m² and about 1% of the total lifecycle GWP. Serrano and Alvarez (2016) studied the impact of two different types of housing topologies on both total lifecycle energy consumption and GWP in Spain. Results reveal that the single-family terraced housing typology consumes nearly 17% more energy and emits 25% more emissions than the multi-family housing typology at the construction stage as multi-family typology allows for more opportunities sharing of common structures and spaces.

Use (B1–7)

The operating phase is the stage where the needs of users are met. During this stage the building is maintained and refurbished throughout its lifecycle to sustain the functional capacity. During this period, the number of repairs, refurbishments and upgrades of building components or services will be required upon demand; while a replacement will replace 100% of a material or component. Replacements may occur several times during the life of the building. All this periodical work will accumulate and require energy to perform and at the same time releasing emissions.

The operating stage of a building entails the energy and emission associated with the cooling, heating, ventilation as well as the lighting, electricity and water supply. There are many variances to the factors affecting a building's operating energy and emissions such as the design of the building, purpose of the building, occupation number, energy source, local climate, building materials type and quality as well as air changes and occupants habits. Ramesh *et al.* (2010) state that the operating stage utilizes approximately 80%–90% of a building's lifecycle energy. Operating energy consumption can either obtained from the analysis of utility bills or use simulation software such as EnergyPlus, AccuRate, ECOTECT to estimate electricity or gas consumption.

The selection and use of materials in building for both the structural elements and interior finishes can influence not only the embodied energy of a building but also the operating energy. Maintenance of a building is required throughout the operating stage and it is where a large variety of building materials that have a lifespan less than that of the building have to be replaced (Ramesh *et al.*, 2010). The actual replacement of materials coupled with the regular maintenance to building components from wear and tear leads to a recurring embodied energy and emissions to occur. Typically the recurring embodied energy and emissions are not associated with buildings structural components as these materials in most cases have a lifespan similar to or longer than that of the building itself. Maintenance and replacement data are difficult to get and highly varies according to the life expectancy of materials, components and systems. Publications such as the study of life expectancy of housing components (NAHB, 2007), the life expectancy of building components (RICS, 2006) and lifecycle costing (AIQS, 2002) are commonly used to study the frequency of maintenance, replacement refurbishment in buildings.

Tables 4 and 5 demonstrate that the use phase consumes the most of energy and generates the most of GWP, approximately 86%–94% and 81%–93% respectively during the building's lifecycle. However, there is no detail information in the studies with regards to whether embodied energy and emission for maintenance and replacement were included in the studies in the tables. Therefore figures in the tables may be higher if the maintenance and replacement of materials or systems are to be allowed for. The study conducted by Carre and Crossin (2015) compared lightweight timber design with the traditional concrete structure for two medium-rise apartment buildings in Australia. Research results indicate that both buildings generate a similar amount of GWP but the product stage of the lightweight construction generates about 32% fewer emissions than the concrete construction. In the study conducted by Serrano and Alvarez (2016) reveals that the multi-family housing typology consumes approximately 23% fewer emissions than the single-family terraced typology.

EOL (C1–4)

Demolition at the end of the building's lifecycle is sometimes inevitable. The most commonly used disposal methods are landfilling, recycling or incineration. The EOL scenarios used are different for different building materials such as landfilling is commonly used for timber while recycling is of steel and concrete (Kellenberger and Love, 2009; John *et al.*, 2009). Incineration is frequently used for timber as wood waste can be burnt for biomass energy.

The EOL phase is important as this is the phase that demolished materials can be recycled to decrease the consumption of energy in the manufacturing of new building materials and reduce to the potential impact on the landfill sites. However, according to Guggemos and Horvath (2005), material recycled, reused or landfilled should not be included in the overall environmental impact assessment of a building for two reasons. Firstly, it is hard to forecast the future value of demolished materials accurately, and whether or not they are appropriate to be reused, recycled or landfilled that they are considered hazardous waste. Secondly, they consider that the recycling of salvaged materials is accounted for in the manufacturing process, and in turn would be accounted for in a future building LCA that uses the recycled materials.

The research conducted by Kellenberger and Love (2009), and John *et al.* (2009) show that landfilled timber has a lower GWP than steel and concrete buildings. Angel and Castle (2007) studied the potential GHG liability of landfill in Australia. It was concluded that there is no future for landfilling wood wastes as they have degradable organic carbon, which decomposes over time and emits GHG when it is landfilled. Therefore future EOL scenarios including incineration with energy recovery (biomass) should start to be adopted more regularly to reduce GHG in the future as every tonne of wood waste disposed into landfill today will be a GHG liability in the future (Angel and Castle, 2007).

The assessment in the impact of EOL phase includes the energy consumed and emission generated by machinery or equipment used during demolition and the average distance of travel by trucks to dispose the waste to the landfill or recycling facilities. From Tables 4 and 5 less than 1% of energy is consumed and about 1%–14% of GWP is emitted during this stage in most of the studies. The study conducted by Wu *et al.* (2012) has the highest EOL impact of GWP, approximately 14% which is much higher than the other two studies of office buildings in the table and from the literature. However there was not enough detail for further examination.

Examples of LCA Studies of Buildings

LCA is a well-developed and useful environmental assessment tool that has been utilized to assess the environmental performance of buildings over their effective life (Bribián *et al.*, 2009). More than 90%–95% of LCA case studies concentrate on assessing environmental impacts within the building sector (Ortiz *et al.*, 2009b). These case studies assist key stakeholders by concentrating on appraising the total environmental impacts and supporting decision-making regarding environmental preferred materials and systems over a building's lifecycle (Chau *et al.*, 2015).

LCA has been used in many studies in the building sector for a complete building or in some studies focusing on the LCA studies of building materials or systems to aid the selection process during the early design stage. Some of these environmental building material studies were based on partial LCAs or cradle-to-gate studies before particular guidelines were introduced to allow for comparative studies based on fixed criteria. Some target one or several stages of the building lifecycle.

Rashid and Yusoff (2015) conducted a review of LCA studies for buildings and summarized that the LCA studies in the construction industry have increased steadily since the 1990s. In another study by Anand and Amor (2017) state that LCA studies have increased more than double in the last five years with 2015 alone about 250 building LCA papers were published. Anand and Amor (2017) continue to state that the LCA studies for buildings have now shifted from focusing from operating phase to a full lifecycle study. Table 6 provides a snapshot of LCA studies from the literature. As also indicated in Table 6 the majority of the LCA studies concentrate on the cradle-to-grave system boundary. The common study period of LCA studies in the table is 50 years lifespan while the functional unit ranges from the whole building assessment to 1 m² of GFA. The total fossil fuel consumption (FFC) and GWP are the two impact categories assessed most of all other impact categories.

The environmental study of building materials or systems are important as results can provide information for the selection of low impact materials or systems to reduce the lifecycle energy consumption and associated impacts. In the table the study by Contarini and Meijer (2015) was to compare several flat roof systems of different materials and thickness of insulations, heat resistance, waterproofing layer and covering layers for an apartment building in the Netherlands. Research results indicate that improving insulation from 2.5 to 5 m² K/W leads to the reductions of the damage scores from about 10%–40%. The outcomes will aid building owners and construction maintenance companies to choose renovation options for flat roofs with the lowest impact on the environment.

Puettmann *et al.* (2010) also documented a cradle-to-gate comparison between hardwood and softwood manufacturing in the US and the result showed that softwood required 50% less energy than hardwood. Kahhat *et al.* (2009) based the LCA framework to analyze the environmental impacts of six different exterior wall systems of a single-storey residential building. Study results indicate that the operating stage of the lifecycle accounts for approximately 94% of total energy consumption. In addition insulated concrete exterior walls consume approximately 700 GJ (5% of total lifecycle energy) than traditional wood frame exterior wall and generate less negative impact to the environment because of the dominance of the use phase in energy consumption. These cradle-to-gate studies are a useful source of data and add to the accuracy of whole building LCA as they continually improve.

LCA studies have also been undertaken to one phase of a building lifecycle which may target for improving the design and construction of buildings. Guggemos and Horvath (2006) analyze the environmental impacts for the construction of structural frame of a university building in California, US. Results reveal that 50% of environmental impacts were related to the use of equipment on-site and the temporary construction materials have the second most significant impact. Bawden and Williams (2015) also conducted research focusing on the operating energy and associated emission for low-rise, medium-rise and high-rise residential buildings in the US. High-rise residential buildings consume the most of energy and associated emissions due to the

energy-intensive structural materials to support the loading of the building. The research results indicate a high energy consumption compared to previous studies due to inconsistent system boundary. Thus the explicit definition of functional unit leads to an increase in the contribution of supply chains to building energy lifecycles.

The table also shows that cradle-to-gate is also a commonly used system boundary in LCA studies. Glover *et al.* (2002) compared the impact of wood, steel and concrete when used in three single-storey houses in New Zealand and resulted in the lower embodied energy of 50% for the timber house over the house with concrete floors and steel frames. Other cradle-to-gate studies are mostly undertaken on building materials or components (Kahhat *et al.*, 2009; Puettmann *et al.*, 2010; Contarini and Meijer, 2015).

Besides conducting LCA studies in a single stage, some research works targeted all the stages in a building lifecycle. As stated by Anand and Amor (2017) LCA studies have shifted to focus on full lifecycle studies than a single phase. LCA studies of residential buildings are common ranged from single-storey to multi-unit apartment buildings such as Adalberth (2000), Adalberth *et al.* (2001), and Zhang *et al.* (2014) are some examples that a full building lifecycle was used in the studies. Results indicate that the operating phase consumes most of the energy and other associated emissions and pollutants. Serrano and Alvarez (2016) focus the

study on the impact of the typology of single-family terraced housing with multi-family housing on total energy consumption and emissions on a cradle-to-grave approach and a study period of 10 years. The findings are important for the future planning and design of residential buildings.

Carre and Crossin (2015) compared two medium-rise apartment buildings of lightweight timber design and traditional concrete structure for six impact categories in Australia. Research results reveal that lightweight design with timber and engineered timber construction has less impact compared with traditional concrete structure. The results have provided information for developers and designers to consider timber and engineered timber as structural materials which are not commonly used in Australia. The results were supported by another study by Thomas and Ding (2018) for ten houses of one to two-storey in Australia. The case studies compared engineered timber with traditional brick construction and results suggest that houses built with engineered timber consume less total lifecycle energy.

Ochoa-Franco (2004) uses an input-output approach to evaluate the lifecycle impact of three residential building in the US and found that the operating energy consumption accounts for over 90% of energy use, electricity use, fossil fuel depletion, and human-health impact categories, and for over 50% of global warming effects and air pollution. Guggemos and Horvath (2005) use LCA to compare environmental impacts of steel- and concrete-framed an office building and realize that the operating stage consumes most of the energy. The research also identifies that the impacts at the construction stage are minimal to approximately 0.4%–11% of energy consumption and emissions in the building lifecycle. The maintenance and EOL also account for a small part. Junnila *et al.* (2006) identify similar results in the evaluation of two new office buildings in Europe and the US from material production through construction, use, maintenance and EOL stage. Results reveal that the operating stage accounts for 70% of energy consumption and emissions.

Wu *et al.* (2012) conduct an LCA study of a high-rise office building in China on the energy consumption and associated CO₂ emissions. Similarly, the operating phase consumes most of the energy and generates most of the CO₂ emissions, within which the highest is the heating and cooling system and followed by the concrete and steel in material production. The research has suggested adjusting the set-point temperature in the operation of an office building and increasing the recycle use of concrete and steel as the main objectives in the future design and construction of office buildings in China.

Limitations of LCA Studies in Buildings

LCA has been significantly developed over the years. It is now a useful decision-making tool for appraising the environmental impacts of a building, material or system (Finnveden *et al.*, 2009; Jeswani *et al.*, 2010). However, the applications of LCA are still complicated and challenging to use. There are limits on sustainable knowledge, especially the comprehensive information supported in the assessment of energy, emissions and water consumed in buildings.

The main limitations in regards to performing LCA studies of buildings are having access to up-to-date data. There is a plethora of data for the various material and fuel inputs that go into a building. Around the world there are a large number of gaps in data as there has no accurate lifecycle inventory data available for all materials in buildings. This is particularly serious for developing countries. Therefore LCA studies have relied on using international data or computer programs such as SimPro or GaBi. The international database or computer programs may suffer from regional variations such as different weather conditions, manufacturing processes and fuel sources.

Scheuer *et al.* (2003) and Verbeeck and Hens (2010) point out that the evaluation of buildings is challenging compared to the evaluation of products. Buildings are larger in scale, complicated in installed materials and service functions, and have a long lifespan. However, the lifetime of some components and service systems is shorter than the building and require refurbishment/replacement during the building's lifecycle. An LCA on the environmental impacts can be made when the building is built, upgraded or refurbished. New technologies used to improve the sustainability of buildings enhance over time but the industry's knowledge is commonly left behind. This means that the industry has limited or outdated information on the impacts from the extraction of raw materials for manufacturing building materials, transportation to the site, construction, use, and disposal processes at the EOL stage (Chan *et al.*, 2014; Berardi, 2015).

Challenges associated with LCAs for buildings are that they contain some stages and each of these stages has some variable inputs including material suppliers, manufacturing processes, delivery modes, energy suppliers, maintenance and demolition. In addition to these specific challenges to construction, there are also limitations such as necessary hypotheses, imperfect data, adaptability issues and high costs (Lei *et al.*, 2003). As there are many different LCA models they are each prone to particular challenges so the method should be chosen to suit the particular product or system environment.

Conclusions

Environmental crises such as shortage of natural resources, ozone depletion, emissions of GHG, and climate changes impacting on the living and working environments mean that the building sector has to be improved to meet sustainability requirements. The construction industry plays a vital role in achieving the goal of ecologically sustainable development as buildings have a high impact on the environment. The development of the LCA approach under the ISO 14040/14044 has provided an objective and systematic tool to analyze energy, emissions and resource consumption in the design and construction of buildings. Current

literature of LCA studies of buildings has demonstrated the use phase in a building's lifecycle is the most important stage as this is the stage that consumes most of the energy and generates the most of emissions. However the literature also reveals that the focus of operating stage of a building is now shifted to the upstream material production phase due to the improvement in operating efficiency of buildings. In most of the LCA studies the product phase in a building's lifecycle is the second largest in the consumption of energy and generation of emissions after the operating phase.

The diverse LCA research method with different goals, scopes and boundaries may impact the accuracy and usefulness of LCA results to facilitate direct comparisons of building materials or components and to optimize building design to enhance low impact in the construction industry. In addition LCA study requires a comprehensive data set which may require constant expansion to include new materials and update to reflect on the latest development in the manufacturing processes and construction technologies. LCA study of buildings is challenging as each building is unique and it also involves a vast investment of resources and has a long lifespan. Therefore it is important that the standardization and transparency of LCA framework are adhered to in LCA studies in the construction industry. The implementation of LCA can help designers, practitioners and decision makers to make informed decisions by providing a comprehensive analysis of the environmental performance of materials and buildings.

Lifecycle Assessment of Building Materials – A Cradle-to-Gate Approach

Grace KC Ding, University of Technology, Sydney, Australia

© 2020 Elsevier Inc. All rights reserved.

Introduction

In recent years the desire to quantify the impact of human activities on the environment has attracted attention around the world, in particular, the activities in the construction of buildings (Takano *et al.*, 2014). The construction of buildings utilizes about 40% of stone, sand and gravel, 25% of timber, 16% of water, and consumes an enormous amount of energy and emits 19% of global greenhouse gases (GHG) annually worldwide (Arena and de Rosa, 2003; IPCC, 2014; Hossain *et al.*, 2017).

In the past, research studies focused on improving operating efficiency as it was regarded as the stage that consumes most of the energy and generates most of the emissions during the building lifecycle. However, energy consumption and emissions due to building operation have been reduced progressively through shifting to the use of renewable energy, and the incorporation of technologies into the design and construction of sustainable buildings (Meggers *et al.*, 2012). The design and production of building materials have now attracted more attention.

To avoid the negative impact on the environment, it is important that the potential impacts of the design and production of building materials are taken into consideration on a lifecycle perspective. The consideration includes the consumption of resources and the damage to the environment caused by the extraction of raw materials, manufacturing and transportation of building materials. Also the recycle content and potential recyclable characteristic of materials should also be considered in the selection process of materials and products for buildings. The durability of the materials and their effect on the entire lifecycle of the building are also important considerations.

Government, industry and research organizations recognize the usefulness of lifecycle assessment (LCA) as a critical tool to identify the potential impacts of materials and products on the environment. The LCA approach is particularly important given the high volume of materials used and the growing importance of environmentally sustainable decisions. For a building, the commonly and traditional used materials are high impacts materials such as concrete, steel, plasterboard. Therefore improving material performance is paramount significant in reducing environmental impacts.

The goal of this article is to review the methodology of LCA of building materials for use in research, policy analysis and building code development. The article begins with a discussion on the importance of materials in a building's lifecycle and the selection criteria, followed by a discussion of the various initiatives and programs related to the evaluation of environmental impacts of materials. This article also reviews the LCA approach in the assessment of environmental impacts of materials on a cradle-to-gate system boundary and includes examples of LCA studies of commonly used building materials. The article ends with a discussion on strategies for reducing environmental load of building materials.

Importance of Sustainable Building Materials

Sustainable development is the foundation of environmentally sustainable practices in the construction industry and within which it provides a framework to develop strategies for buildings to be designed and built by shifting from the use of conventional resources to the use of renewable-based resources. The selection and use of materials in buildings have caused severe environmental impacts associated with the extraction and consumption of raw materials during the entire lifecycle of buildings. In achieving the goal of sustainable development in construction, the production and selection of low impact and environmentally friendly building materials are essential.

With the reduction of operating energy and emissions, the energy and emissions embodied in materials are now attracting more attention in research and development as they are permanent and take immediate effect from when the raw material is extracted and manufactured (de Wolf *et al.*, 2016). Huisinigh *et al.* (2015) state that the emissions embodied in materials in the cradle-to-gate stage account for between 88% and 96% of the total lifecycle emissions. The increased attention on reducing energy and emissions in the material is challenging but can be achieved by shifting to the use of low impact materials and correspondingly changing the perspective people have on these building materials (Meggers *et al.*, 2012).

The impacts of materials have on the environment depend on the length of the lifecycle studied, types of buildings, types of energy used and the related technologies employed within a building. According to Chau *et al.* (2015) conventional commercial buildings are about 10%–27% of the total energy use and carbon emissions with a lifespan of 50 years while residential buildings are about 15%–40%. They go on to state that the building structure is found to have a profound impact of the resources and emissions content due to the vast quantities of materials used in the construction. The percentage tends to become higher with a shorter studied lifespan.

Research studies shown that the material phase has more profound impact than operating phase on zero energy or zero emission buildings. Zero or low energy buildings consume less operating energy in the use phase due to the design and technological advancement (Basbagill *et al.*, 2013). Therefore it increases the importance of energy and emissions embodied in

materials. According to [Chau et al. \(2015\)](#) the energy and emissions embodied in materials of net-zero energy buildings were found to have about 78% of the total in a building's lifecycle. The research further reveals that a passive house with photovoltaic installation was found to be 44% more than its operating energy in a 60 year lifespan and 56% for a 100 year lifespan. [Thiel et al. \(2013\)](#) analyze the environmental impact of a net-zero energy building and found that the most significant environmental impacts were in the structure made from concrete and structural steel. [Haapio and Viitaniemi \(2008\)](#) examine different structural design and material use of 78 single-family houses and results indicate that material production phase has the highest environmental impact for new buildings.

Presently, the construction industry is facing challenges regarding the delivery of sustainable buildings. Significant portions of a building's lifecycle impacts are determined by decisions made in the selection of materials at the early stage of design development. Therefore, choosing materials with low impacts at this stage has the potential to reduce the overall lifecycle impact significantly. For this purpose, it is crucial that both material manufacturers and designers take into account the potential effects and magnitude of the impact of materials on the environment at an early design stage of a building.

An LCA approach is particularly important in this respect as it provides a systematic assessment of the full range of impacts of materials on a lifecycle perspective. The aim of LCA in the first place is to compare the environmental impact of different raw materials and processes that have the same function but have lower impacts. LCA can be used as a decision-making instrument in the design and production of new materials. In choosing materials for buildings, the following criteria are to be taken into account in the design process:

- (1) Materials with recycled content – The use of materials is closely related to the total embodied energy and emission during production processes. The use of materials with recycled content can potentially reduce embodied energy and emissions compared to the manufacturing of using new materials. [Thormark \(2002\)](#) conducts a research study of an energy efficient apartment building in Sweden for a lifespan of 50 years and research results indicate that the recycling potential can reclaim up to 15% of the total energy used.
- (2) Low emission during manufacturing – Emissions are related to the manufacturing process of building materials that may have adverse effects on the environment. This will require the selection and use of building materials with the lowest negative impacts on the environment. Therefore, the environmental performance data of materials from the LCA results and eco-labeling can be useful and important in the selection processes.
- (3) Low energy intensity – Energy is required in the entire supply chain in the production of materials. The production and use of energy affect both the natural and manmade environment through the resulting pollutants and depletion of resources. Therefore the consideration of low energy intensity materials is one of the most important criteria that should be taken into account in the design and construction of buildings.
- (4) Biological content – The biological criterion takes into account the effects of materials on the health and wellbeing of users during the use phase of a building. The knowledge of the risks that old and modern building materials pose to health is essential to ensure the protection of the environment and users.

Initiatives, Certification Systems and Government Regulations for the Assessment of Environmental Performance of Materials

In response to the climate change and environmental degradation, governments and international organizations have developed policies, regulations and standards to reduce impacts of buildings on the environment. The European Union Energy Performance of Building Directive ([Gieseckam et al., 2016](#)) and the Australian National Construction Code Section J ([ABCB, 2010](#)) have been issued to regulate the improvement in the design and construction of building fabric performance for energy efficiency. However, these policies and regulations principally focused on the operating emissions associated with energy consumption for heating and cooling, lighting, and ventilation but have not been extended to the embodied energy and emission associated with the initial production of building materials and products.

The International Organization for Standardisation (ISO) standards is the most important one in providing consistency, transparency and credibility in the assessment, monitoring, reporting and verification of performance for buildings and materials ([ISO, 2006a,b](#)). The ISO 14040/14044 Standards focus on establishing principles and framework and providing requirements and guidelines for the LCA study ([ISO, 2006a,b](#)). The four steps of assessment in the LCA framework have been applied to standardize and quantify the environmental performance of materials ([Finkbeiner, 2014](#)).

In addition to the establishment of the ISO Standards, quantifiable impact such as carbon footprint (CF) and eco-labeling have also been developed as labeling systems to provide environmental performance data of materials and products. These systems are primarily voluntary but can raise awareness about environmental problems and leads to the competition in the material manufacturing industry. CF has been widely used to measure the total amount of GHG emissions of materials and products that both upstream and downstream emissions are accounted for. It is usually expressed in an equivalent value per mass of CO₂ for the GHGs such as N₂O and CH₄ in materials and products ([Basu and Bidanda, 2014](#)).

Eco-labeling for materials has been developed almost in every country now. The purpose of eco-labeling of materials is to promote the supply of materials with lower environmental impacts through verifiable and reliable information and to stimulate manufacturers to improve material performance environmentally. Eco-labeling was initiated by the Global Ecolabelling Network

Table 1 Three types of eco-labeling for materials and products

Type	ISO	Example	Purpose
Type I Third-party ecolabel	14024 (1999)	EU Eco-label, Nordic Swan (Nordic countries), Blue Angel (Germany), Environmental Choice (Australia)	To promote and identify products of the best environmental performance achieved in the market
Type II Self-declared environmental claims	14021 (1999)	In the form of written statements or symbols, e.g., CFC-free, recycled content	To provide environmental performance of products or services
Type III Environmental product declaration (EPD)	14025 (2006)	IBU-EPD Program (Germany)	• To provide independent verification of claims that contain relevant and verifiable LCA information based on the ISO 14040 series of standards • To facilitate environmental comparison between products that perform the same function

Sources: Vigovskaya, A., Aleksandrova, O., Bulgakov, B., 2017. Life cycle assessment (LCA) in building materials industry. MTEC Web of Conferences, 106, 08059, SPbWOSCE-2016 https://www.matec-conferences.org/articles/mateconf/pdf/2017/20/mateconf_spbw2017_08059.pdf. Logon: 15/7/2018.

in 1994 to improve and develop labeling systems of materials and products worldwide. According to the [Global Ecolabelling Network \(2018\)](#), there are more than 463 eco-labeling organizations in 199 countries in over 25 business sectors.

Table 1 summarizes the three types of eco-labeling for materials and products. The three types of eco-labels are developed in according to the ISO standards. Type III eco-label is particularly important as it has to be prepared in according to the rules and requirements of the Product Category Rules which are key part of ISO 14025 to enable transparency and comparability between environmental product declarations ([Vigovskaya et al., 2017](#)). However, the exceedingly supply of eco-labels has abused and misused to claim environmentally friendly materials by manufacturers or suppliers. This is particularly serious for the Type II eco-labels as these labels are developed directly by manufacturers without the certification by a third-party. Some of these labels are based on the LCA approach but this information may not publicly available due to confidentiality ([Basu and Bidanda, 2014](#)).

The use of eco-labeling for the individual material may be informative but is particularly challenging to quantify the environmental impacts of building materials as building materials are functioned together to achieve the stated performance in the design. For example, the effective use of insulation in the building design can result in less energy consumption and better user comfort during the use phase, but its manufacture may involve the release of pollutants ([Basu and Bidanda, 2014](#)). Also building materials require transportation from distribution centres to site that the impact may be significant if sourced from overseas. However, locally harvested raw materials may affect the local ecological systems ([Basu and Bidanda, 2014](#)).

Life Cycle Assessment (LCA) for Building Materials

In the past, environmental studies have focused on the operating stage as this stage represents the majority of energy consumption and emission during a building's lifecycle. However, more attention has now been shifted to the environmental impacts of raw material extracting, manufacturing and transportation ([de Wolf et al., 2016](#)). The assessment of the impact of building materials is similar to an LCA study of a building. The principal objectives of LCA are to quantify and evaluate the environmental performance of materials so that decision-makers can compare and select materials with the least impact on the environment. Additionally, LCA provides a basis for assessing potential improvements in the performance of materials to reduce their overall environmental impacts. This can be done in an overall sense or targeted to improve specific stages during the lifecycle.

Over the years LCA has been used to conduct detail analysis and comparison of the environmental impacts of numerous building materials. [Cole \(1999\)](#) conducts an LCA study on comparing the use of wood, steel and concrete structural assemblies and found that wood has the least impact compared to steel and concrete structure. [Wei et al. \(2008\)](#) use LCA to investigate energy and emissions for different building components while [Goggins et al. \(2010\)](#) investigate to replace Portland cement with blast furnace slag and results indicate a reduction of energy consumption and emissions in the production of concrete. [Mao et al. \(2013\)](#) study the use of industrialized methods of construction and found that prefabrication has lower emissions than traditional methods of construction.

The LCA Framework for Material Assessment

The lifecycle environmental impacts of building materials according to LCA is usually conducted on a 'cradle-to-gate' boundary as indicated in [Fig. 1](#) which presents a building lifecycle stages in according to the CEN 15978 ([CEN, 2011](#)). The LCA study for building materials based on a cradle-to-gate system boundary involves mainly the upstream processes of raw material extraction and associated processing activities ([Hafliger et al., 2017](#)).

Building lifecycle stage															
Product stage			Construction process stage		Use stage							End-of-life stage			
Raw material supply	Transport	Manufacturing	Transport	Construction/Installation	Use	Maintenance	Repair	Replacement	Refurbishment	Operational energy use	Operational water use	De-construction/Demolition	Transport	Waste processing	Disposal
A1	A2	A3	A4	A5	B1	B2	B3	B4	B5	B6	B7	C1	C2	C3	C4

Fig. 1 Lifecycle stage of buildings. *Source:* Adapted from CEN, 2011. Sustainability of Construction Works – Assessment of Environmental Performance of Buildings – Calculation Method. British Standard Institute.

The A1 stage in the CEN 15978 is the raw material supply stage. This stage includes the extraction of raw materials and the associated processing activities from the ground. The A2 stage is the transportation of the extracted raw materials to the factory gate either locally or overseas for the manufacturing of building materials and products. The manufacturing (A3) is the final stage of the Product Stage in a building's lifecycle. This stage involves the manufacturing of raw material into materials and products for buildings.

Energy is required at each stage of the Product Stage. Energy is consumed to operate machinery and equipment for the raw material extraction activities at the A1 stage and the manufacturing processes at the A3 stage. Energy is also required for the transportation (A2 stage) of raw materials and different transportation modes may require different fuel types. The energy consumption at these stages generates a significant amount of energy-related emissions and other pollutants such as dust, noise and contaminants which have a significant impact on the environment (Buyle *et al.*, 2013; Vigovskaya *et al.*, 2017).

LCA study for building materials ends at the production of materials and products at the factory gate and further downstream activities are not part of the cradle-to-gate boundary. Therefore the following stages are outside scope of the LCA study of building materials:

- Construction process stage (A4–5) – Transportation of finished materials and products between manufacturer and building site, and construction activities on-site.
- Use stage (B1–7) – This stage usually refers to the operating and use of buildings. Building materials and products may only be used during repair, replacement or refurbishment during the operating stage of a building.
- End-of-life stage (C1–4) – Similarly, this stage refers to the final stage of a building's lifecycle which may involve eventual demolition and disposal. Some of the salvaged materials may be recycled or reused in the manufacturing process of building materials or components.

The Application of the ISO Standard for the LCA Study of Building Materials

The ISO standard is central to the LCA study of building materials. Fig. 2 illustrates the four steps of the LCA framework and the cradle-to-gate boundary of building material production (shown dotted lines). The four steps are generic for either a whole building LCA study or an LCA study of individual materials. According to the ISO 14040/14044 the LCA framework for material assessment begins with the goal and scope definition. This is the stage that objectives of the study are established so that boundary can be defined and functional unit to be set. For an LCA study of building materials the goal is to determine the environmental impacts from the production of materials and products and the scope of the study focuses on the raw material acquisition, processing and manufacturing.

The second step as indicated in Fig. 2 is related to the development of the lifecycle inventory (LCI) of the material studied. The LCI activities include quantifying the input and output flows of raw materials and energy and analyzing environmental impacts to the production of material in the study. The usefulness of an LCA study is highly dependent upon the accuracy and comprehensiveness of the LCI. Without a reliable and broad LCI, the usefulness of an LCA study may endure and uncertainties may be introduced to the lifecycle impact assessment (LCIA) stage. As illustrated in Fig. 2 the LCI stage of an LCA study of building materials includes identifying and collecting input and output flows in the supply chain of material production. The input flow involves the consumption of raw materials, energy and water. The output flow includes the production of the principal material and the generation of emissions, waste and by-products.

The compilation of data for the LCI can be developed using computer software such as GaBi, SimaPro for product comparison. Commercial and open access databases also exist and provide comprehensive information on environmental impacts of materials and products for developing the LCI. The databases that are commercially available include Ecoinvent or free access such as USDA, openLCA, NEEDS (NEXUS, 2018). However, base the study on different tools and databases may result in different outcomes.

International Standards Organization, Geneva. ISO, 2006b. ISO 14044: Environmental management – Life cycle assessment – Requirements and guidelines. International Standards Organization, Geneva.

Table 2 Selected impact and damage categories in LCA study of building materials

<i>Impact category</i>	<i>Units</i>	<i>Damage category</i>
Acidification potential	kgSO ₂ eq	Ecosystem
Eutrophication potential	kgN eq	Human health & ecosystem
Global warming potential	kgCO ₂ eq	Ecosystem & fatalities
Ozone depletion potential	kgCFC-11 eq	Human health & ecosystem
Ecotoxicity	kgLC ₅₀ eq	Ecosystem
Human toxicity	kgLC ₅₀ eq	Human health & fatalities
Fossil fuel depletion	MJ	Human health & fatalities
Photochemical ozone formation	kgC ₂ H ₄ eq	Human health & fatalities

Source: Adapted from IPCC, 2014. Climate change 2014: Impacts, adaptation, and vulnerability. In: Field, C.B., Barros, V.R., Dokken, D.J. (Eds.), Part A: Global and sectoral aspects. Contribution of Working Group II to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change. Cambridge: Cambridge University Press.

Takano *et al.* (2014) conduct a research study to examine the numerical and methodological differences of five databases of GHG emission values in the material production phase of five housing projects. Research outcomes reveal that the databases generate different results but show similar trends and the same order of magnitude differences shown by all the databases. Therefore the selection of a database that is relevant to the regional condition and climatic similarity is critical.

The LCIA stage involves the classification and characterization of impacts identified in the LCI stage as illustrated in Fig. 2. The classification of impacts is to sort inventory parameters according to the type of environmental impacts they are contributed to (selected impact categories are included in Table 2), while characterization is to quantify intensity and degree of environmental impacts to each type of impacts such as global warming potential (GWP) is the total of all GHG emissions in materials. Table 2 extracts the common types of impact categories and the associated damage categories in relation to the production of building materials. At the LCIA stage for the LCA study of building materials the impacts are divided into mid-point and end-point category (Fig. 2). At the product stage of building materials the study may focus on all or some the mid-point or end-point impact categories.

The normalization may also be undertaken if impacts are to be standardized or ranked. However, normalization is an option only in according to the ISO 14040/14044. At the end of the assessment, the results are interpreted and conclusions are drawn for product improvement. The improvement can include changing the design and specification of the product to be more energy efficient and fewer emissions on the environment. The LCA results are capable of identifying the key areas for improvement.

Assessing Environmental Impact of Building Materials

Environmental impact (EI) at the product stage takes into account the extraction and consumption of raw materials from the ground and the associated energy in the manufacturing processes and transportation. The process of assessing the EI of individual building materials consists of identifying and collecting input flow of energy use, raw materials and other utilities, and the output flow of product, co-product emissions and waste. The amount and types of inputs used in the production of building materials are assessed according to the total quantity of raw materials needed to fit the functional unit adopted. The calculation of EI of individual building materials requires the quantities per functional unit such as 1 kg of steel, 1 m² of the gross floor area of a building, 1 m³ of concrete. Therefore the calculation of EI of individual building materials is derived by multiplying the quantity of all the raw materials (including wastage) with corresponding EI data in the production of the building material per designated functional unit.

The amount of by-products and emissions associated with the production of building materials and products is highly dependent on the type and efficiency of machinery and equipment used in the extraction and manufacturing process (Chau *et al.*, 2012). The EI computation for energy consumption and emissions is calculated by summing up the duration of machinery and equipment used multiplied by fuel consumption per type and the associated emission coefficient of fuel consumption.

In addition to the energy required to operate machinery and equipment, raw materials are to be transported to the factory gate or finished products to the distribution centres by different modes of transportation. Raw materials transported to factories or distribution centres are delivered via trucks covering the outward trip (usually full load) and return trip (empty). The emissions about transportation are directly related to the efficiency, fuel type, number of truckloads, total distance travel (outward and return trip), fuel consumption and emission coefficient per fuel type (de Wolf *et al.*, 2016). There are various issues of transportation of raw materials that are not extracted locally which are often shipped or by rails from across countries or even from overseas. It is considered that the impact on cross-boundary air qualities and the estimation of EI are much more complicated.

Some Examples of LCA Studies of Building Materials

Cement Material

Cement is commonly used in the construction industry. It is an inorganic and non-metallic substance with hydraulic binding properties, and is used as a bonding agent in building materials. It is used as a component in concrete, mortar, stucco and grout. It is made by heating a mixture of limestone and clay to a temperature of about 1450°C. The product is then grinded to a very fine powder to become cement. During the heating process CO₂ is released from the limestone to produce cement.

The production of cement is an energy intensive process and adversely affects the environment in the form of GHG emissions (Basu and Bidanda, 2014; Hossain *et al.*, 2017). Half of the CO₂ emissions are from the manufacturing process through the combustion of fossil fuel and the rest comes from the calcination of limestone. According to Hossain *et al.* (2017), the production of cement in the world contributes to approximately 5%–10% of the total CO₂ emissions and consumes approximately 12%–15% of total industrial energy use. Overall, for the production of one tonne of Portland cement clinker approximately 0.87 tonne of CO₂ is released into the atmosphere (Hossain *et al.*, 2017). However, this value may vary with the location, technologies used, plant production efficiency, mix of energy sources used and the selection of kiln fuels (Josa *et al.*, 2007).

Fig. 3 summarizes inputs and outputs in the LCA study of the cement production. During the manufacturing process both direct and indirect impacts are considered in the LCA study. The inputs in the production of cement include lime, silica, iron, alumina and small amounts of additives. Approximately 1.6 tonnes of raw materials are needed to produce 1 tonne of cement primarily because of calcination of calcium carbonate, which typically comprises 75%–80% of the raw materials (Huntzinger and Eatmon, 2009). The composition of raw materials varies according to the required properties. The inputs also include the consumption of energy from the combustion of fossil fuels, e.g., coal, gas, oil and renewable energy sources may also be involved in the production processes.

The outputs of the product phase include the production of the cement or clinker. The production processes generate emissions to air, solid waste, waste heat and other by-products. Emissions are generated during the production of cement from the burning process and the diesel trucks. Other emissions include particulate matter from the point and fugitive sources and the combustion gases of CO₂, SO₂, NO_x, carbon monoxide, volatile organic compounds and methane. Solid wastes include cement kiln dust from the production of cement. According to Hossain *et al.* (2017), approximately 1.9 GJ of heat lost per tonne of cement produced. This is heat lost primarily in the kiln and cooler exhaust gases and also by radiation from the kiln shell and other hot surfaces.

The Portland Cement Association initiated to develop LCA-based EPD for three types of cement and they are Portland cement, masonry cement and blended cement (Portland Cement Association, 2016a,b,c). The LCA results are summarized in Table 3. From the table the traditional Portland cement has the most significant impact in all categories and followed by blended and masonry cement. The blended cement is manufactured by mixing Portland cement with mineral admixtures such as fly ash, slag or silica fumes. The masonry cement is mixed with plasticizing materials and other performance-enhancing additions to form mortar for brick, concrete block and stone masonry.

Other LCA studies have also been undertaken to improve the environmental performance of traditional Portland cement. Huntzinger and Eatmon (2009) use LCA to evaluate and compare four cement manufacturing processes on a cradle-to-gate boundary. Research results show that replacing approximately 25% of clinker with natural pozzolans in the

Fig. 3 LCA framework for the production of cement. *Source:* Adapted from Huntzinger, D.H., Eatmon, T.D., 2009. A life-cycle assessment of Portland cement manufacturing: Comparing the traditional process with alternative technologies. *Journal of Cleaner Production* 17, 668–675.

cement manufacturing process has effectively reduced the most substantial environmental impact process (the kiln or pyroprocessing step) by 22%.

Concrete Material

Concrete is a traditional heavy material used widely in buildings. Concrete is commonly used for load-bearing structures which are high in energy intensity and GHG emissions. Concrete is produced by mixing cement with aggregate, sand, water and other admixtures which are then poured into timber mould to form a designed structure. The characteristic and strength of concrete are controlled by the ratio of water to cement and the types of admixtures.

Concrete has a special characteristics to absorb CO_2 from the atmosphere. This is a process of carbonization that CO_2 diffuses back into the concrete and reacts with calcium dihydroxide (H_2CaO_2). The rate of carbonization depends on the CO_2 concentration and humidity in the ambient air. Since carbonization is gas diffusion the process is slower with increasing humidity. It also depends on the density of the concrete (water to cement ratio) and whether the surfaces coated such as painting or wallpaper that may reduce the rate of CO_2 diffusion into the concrete. According to Chau *et al.* (2015), the net CO_2 emission of concrete production after taking into account both calcination and carbonation was estimated to be $0.033 \text{ kgCO}_2/\text{kg}$ concrete.

The inputs and outputs in the LCA study of concrete are presented in Fig. 4. The inputs for the production of concrete require cement, sand, aggregates and admixtures. Cement is required as a bonding agent to bind all the resources together when mixed with water to form

Table 3 Environmental impacts of cement (1 tonne)

Environmental impact	Portland cement	Masonry cement	Blended cement
Global warming potential (100 year) (kgCO ₂ eq)	1040	692	892
Acidification potential (kg SO ₂ eq)	2.45	1.83	2.26
Eutrophication potential (kgN eq)	1.22	0.93	1.11
Ozone depletion potential (kg CFC11 eq)	2.61E-05	2.18E-05	2.48E-05
Primary energy consumption (MJ)	5887	4611	5243

Fig. 4 LCA framework for the production of concrete. Source: Adapted from Chau, C.K., Hui, W.K., Ng, W.Y., Powell, G., 2012. Assessment of CO₂ emissions reduction in high-rise concrete office buildings using different materials use options. Resources, Conservation and Recycling 61, 22–34.

the designed structure in buildings. Sand and aggregates are produced from crushed stone and concrete mix determines the quantities of coarse and fine aggregates. Admixtures such as air entraining, water reducers, accelerators, superplasticizers are widely used in concrete to control the properties and performance but are usually below 1%. Water is needed in the production of concrete which may be affected by the type, location and size of the plant. Water is also used for truck wash out and off the site and the concrete plant.

Energy is used in the concrete plant that includes electricity and fuel used for equipment and heating. Energy is also required for the transportation of materials, e.g., cement, fly ash, aggregates from distribution centres to the concrete plant which can be by road rail or barge using diesel fuel or others.

The outputs at the concrete production stage include generating emissions in the making of coarse and fine aggregates from crushed stone, cement production and the final production of concrete. Emissions also generate from the consumption of diesel fuel by trucks and are calculated from the energy consumption in the same way as in the LCA study of cement in the previous section. Solid wastes are generated during the extraction of raw materials and the manufacturing processes. Waste heat is also produced in the manufacturing process of concrete.

The National Ready Mixed Concrete Association (NRMCA, 2014) developed EPDs for various types of concrete using an LCA approach and results are summarized in Table 4. The table presents the results of cradle-to-gate LCA results for two types of product

Table 4 Environmental impacts of concrete (1 m³)

Environmental impact	281.2 kg/cm ² (27.6 MPa)	562.5 kg/cm ² (55.1 MPa)
Global warming potential (100 year) (kgCO ₂ eq)	432	633
Acidification potential (kg SO ₂ eq)	2.29	3.34
Eutrophication potential (kgN eq)	0.068	0.094
Ozone depletion potential (kg CFC11 eq)	5.61E-06	8.27E-06
Primary energy consumption (MJ)	2646	3678
Raw materials (kg)	2449	2495
Freshwater (m ³)	21.2	17.6
Waste generated (kg)	0.73	0.73

mix designs considered within each compressive strength class on 1 m³ of ready-mixed concrete. The LCA results show that the environmental impacts increase to the higher compressive strength of concrete.

Table 5 presents the results in percentage distribution by the three stages of the product phase for the compressive strength of 27.6 MPa and 55.1 MPa. The table shows that the percentage distribution of the raw materials production has the highest in both the global warming potential (GWP) and primary energy demand (PED) which agree with the research undertaken by [Hafliger et al. \(2017\)](#). Overall the upstream materials production accounts for approximately 93%–94% and 84%–90% respectively for GWP and PED associated with the production of ready-mixed concrete. The highest percentage in the A1 stage is due to the manufacture and use of Portland cement which is high in both emission and energy consumption. Materials transportation according to [Vigovskaya et al. \(2017\)](#) and **Table 5** contributes about 4% of the GWP and 7%–10% of primary energy consumption. The manufacturing stage according to [Buyle et al. \(2013\)](#) and **Table 5** contributes the least in both.

Steel Material

Steel is another commonly used material in the construction industry. Steel is combined with concrete to form a reinforced concrete structure for buildings. Steel can also be used as raw materials to make components such as window frames, pipes, machinery and household goods. Steel production is a high energy intensity and GHG emissions. The manufacturing processes of steel involve the extraction of iron ore from the ground which then goes through the melting process in a furnace with oxygen blowing through it to remove impurities and reduce carbon percentage to produce steel. The various industrial processes of iron, coke, sinter and steel production contribute to more than 60% of the total energy-related GHG emissions, of which iron production is the largest (74%) ([Olmez et al., 2016](#)). According to [Quader et al. \(2016\)](#) one tonne of steel manufacturing emits approximately 1.8 tonnes of CO₂.

Improving efficiency in the manufacturing process of steel has been the focus of research and development. Steel has sustainable characteristics which can be recycled entirely and used infinitely. The production of steel can incorporate recycled content and reusing water for cooling purposes. Emissions to the air from the production can also be controlled through better design production technologies. Recycled steel (scrap steel) comes from demolished structures, end-of-life vehicles and machinery. According to [World Steel \(2018a\)](#), it was estimated that 630 million tonnes of scrap steel were recycled in 2017 and of this, approximately 560 million tonnes were used by the global steel industry.

The inputs and outputs in the LCA study of steel are presented in [Fig. 5](#). The inputs in the production of steel include the use of 98% of iron ore, small amount of other elements such as manganese, carbon and coal as the primary energy sources. According to [World Steel \(2018b\)](#), the global steel industry used about 2.1 million tonnes of iron ore, 1.1 million tonnes of metallurgical coal and 560 million tonnes of recycled steel to produce about 1.7 billion tonnes of crude steel in 2017. The steel use is projected to increase by 1.5 times to meet the needs of population growth.

Steel production is energy intensive due to the chemical energy required to reduce iron ore using a carbon-based reducing agent. Iron ore and metallurgical coal are used mainly in the blast furnace process of ironmaking. Typically it takes about 1.6 tonnes of iron ore and around 400 kg of coke to produce one tonne of pig iron ([World Steel, 2018b](#)). Improvements in energy

Fig. 5 LCA framework for the production of steel. *Source:* Reproduced from World Steel, 2018b. Life cycle inventory study, World Steel Association, Beijing, China.

efficiency have led to the reduction of about 60% in energy required to produce 1 tonne of crude steel since 1960. The energy efficiency of steelmaking facilities vary depending on production route, type of iron ore and coal used, the steel product mix, operation control technology and material efficiency.

The outputs at the product phase of steel production include the final production of steel but the processes generate various types of emissions, solid wastes, waste heat and other by-products. Similar to the production process of cement and concrete as previously discussed, emissions due to the combustion of fossil fuels in both the manufacturing processes and transportation are also included in the LCA study. The production of steel also generates by-products such as slags, dust and sludge. On average the production of 1 tonne of steel will result in 200–400 kg of by-products. About 90% of the by-products are slags which are solid wastes from the burning processes.

EPDs have been used to provide information on environmental impacts with regards to the production of steel. [Table 6](#) extracts and compares the EPDs for steel production of three different types of steels. The production of hot-dip galvanized steel generates the highest GWP and PDE and followed by hot rolled coil steel. The table also extracts the potential benefits of recycling of the steel at the end-of-life. According to [World Steel \(2018a\)](#), the rate of recycling of steel from the construction industry is approximately 80% which can be recycled as scrap steel in the production of crude steel. From the table hot-dip galvanized steel generates marginally better recycling benefit than the hot-rolled coil steel in both GWP and PED.

Sustainable Building Materials

The design and construction of buildings conventionally focus on using heavy materials such as steel, concrete and masonry but these materials are both high energy intensity and emission content. Therefore over the years research studies focus on using low impact alternative materials, improving technologies and practices to reduce the negative impact of materials on the environment.

Use Low Impact Materials

Construction materials are important for the survival of the industry. However, it is essential that the manufacturing processes of these materials be improved to reduce their impact on the environment. Low impact materials, therefore, play an important role and their selection at an early design stage should be undertaken as it will influence all downstream processes in achieving sustainability in buildings ([Shen et al., 2010](#)). Majority of low impact materials are manufactured from the natural or renewable sources such as timber, straw bale and earth. These materials have low in energy intensity and emissions compared with conventional heavy materials. However, [Giesekam et al. \(2014\)](#) suggest that instead of just replacing conventional materials with

Table 6 Environmental impacts of steel (1 tonne)

Environmental impact	Section		Hot-rolled coil		Hot-dip galvanized	
	Cradle-to-gate	Recycling benefit	Cradle-to-gate	Recycling benefit	Cradle-to-gate	Recycling benefit
Global warming potential (100 year) (kgCO ₂ eq)	1.5	– 0.3	2.2	– 1.2	2.7	– 1.3
Acidification potential (kg SO ₂ eq)	0.0042	– 0.0006	0.0054	– 0.0023	0.0065	– 0.0025
Eutrophication potential (kgN eq)	0.00032	– 0.00005	0.00046	– 0.00017	0.00059	– 0.00018
Photochemical ozone creation potential (kgC ₂ H ₄ eq)	0.00064	– 0.00015	0.00091	– 0.00054	0.00101	– 5.80E-04
Primary energy demand (MJ)	18.3	– 2.8	23.3	– 10.1	29.5	– 10.7

Source: Adapted from World Steel, 2018b. Life cycle inventory study. Beijing: World Steel Association.

natural materials they can be combined to form low impact products such as panelized prefabricated timber and straw bale systems, lime and gypsum to replace convention cement plasters, timber and steel hybrid structures in buildings.

Advancement in the Material Production Technologies

Conventional heavy materials tend to have a long lifespan and require little maintenance and replacement throughout the building lifecycle. However, these materials are both high in energy intensity and emissions that are detrimental to the environment. There are research studies on the improvement of their manufacturing processes to reduce their impacts on the environment. Cement is a mostly used material in the construction of buildings. [Gao et al. \(2015\)](#) state that the production of cement is responsible for about 7% of total CO₂ emission globally. [Ishak and Hashim \(2015\)](#) further state that the clinker production generates about 90% of the CO₂ emissions in the production of cement. Therefore minimizing the need for carbon-intensive cement products is an essential part of reducing the embodied emissions of construction materials ([Giesekam et al., 2014](#); [Gao et al., 2015](#)). The improvement in the production technologies of cement includes recovering waste heat, substituting fossil fuels with renewable energy sources, substituting low carbon cement by cementitious materials such fly ash, silica fume, slag, etc. ([Crossin, 2015](#)). [Gao et al. \(2015\)](#) further state that GHG emissions can be reduced by replacing carbonate-containing materials with non-carbonate materials and changing the clinker ratio in cement production.

Steel is another commonly used and high impact building material. Improvement in the steel production has attracted much attention to reduce the consumption of raw materials and emissions. Improvements include capturing and reusing gas and waste heat, collecting and recycling waste steel to reduce the use of virgin materials, improving the quality of steel products to maximize the lifespan, using energy-saving equipment, and improving the efficiency of energy conversion facilities ([Quader et al., 2016](#)). In the production of concrete solid waste such as use waste glass cullet from waste glass bottles to substitute clinkers can be used to replace virgin materials to produce eco-glass cement. According to [Hossain et al. \(2017\)](#), eco-glass cement has about 16% energy consumption and 17% GHG emission compared to that of traditional Portland cement but comparatively similar strength.

Use Lightweight Building Structures

The design and construction of buildings can be shifted to focus on using lightweight materials ([Meggers et al., 2012](#)). [Meggers et al. \(2012\)](#) go on to state that lightweight building designs can minimize the consumption of raw materials and the structural design of concrete with expanded aggregates can reduce the overall weight as well as improving insulation property of the building. [Giesekam et al. \(2014\)](#) further suggest to use lightweight design in conjunction with structural member optimization to minimize the excessive use of materials but this will require changes in design practices or innovative manufacturing processes. [López-Mesa et al. \(2009\)](#) compare environmental impacts between in-situ and precast concrete floors for two seven-storey residential buildings. Research results indicate that precast concrete floor with a longer span between beams reduces the size of columns and footings and thus reduces the total concrete used in the building which has about 12% lower environmental impact than in-situ concrete.

Use Alternate Fuels

Majority of the energy sources are fossil-based such as oil and coal which are high in emissions. Bio-based and industrial by-products such as waste plastics, scrap tires, wood residues, biomass wastes, wood chips, palm shells, saw dust and so forth can be used as alternative fuel sources in the production of building materials. These waste materials, on the one hand, can be used as fuel to replace fossil fuel, on the other can reduce waste to landfill sites. [Hossain et al. \(2017\)](#) conduct a research study to compare the manufacturing process of four different types of cement. Research results indicate that by replacing 10%–50% of coal with the biofuel produced from locally generated wood wastes, potentially 3%–14% and 6%–29% of total GHG emissions and non-renewable energy consumption can be reduced respectively in the production of one tonne of traditional Portland cement.

Increase Reuse and Recycling of Materials

The construction industry is an industry slow to change. Significant concept changes in the practices of the construction industry to facilitate the reuse and recycling of building materials can be made possible if they can be considered as early as possible in the design development. Such changes could be made to favour the disassembly of the construction materials at the end of their service life and by selecting materials for the recycled sources and assembly, techniques are significant in the reduction of GHG emissions (Bribian *et al.*, 2011). Giesekam *et al.* (2014) state that increased reuse and recycling will require design for disassembly and an increased focus on the end of life project stage during design. Proper early planning in the design and construction of buildings is essential.

Conclusion

Building materials are used for the initial construction of a building and will continue to be consumed during the use phase for maintenance and refurbishment. The production of building materials is both high energy intensity and GHG emissions throughout a building's lifecycle. The building materials while important for the construction industry they are also potentially significant in minimizing environmental loads as materials are used throughout the building lifecycle. To reduce the environmental impact of buildings, it is necessary to design and select materials with low impact to reduce resources consumption and GHG emissions.

This article provides an overview of the importance of building materials and discusses the framework of LCA in the assessment of material on a cradle-to-gate boundary. LCA provides a systematic and transparent framework to generate data to assist the selection of environmentally friendly materials for buildings. Through the LCA analysis, all possible environmental loads of material are ultimately assessed and classified according to their contribution to the environmental impact and damage categories. While LCA can be applied to compare the environmental impact of different materials, it can also be applied to different production processes to determine the stages causing the most significant environmental harm for improvement in a lifecycle perspective.

Over the years significant research and development have been undertaken to improve the manufacturing processes of materials. The common suggestions are substituting high impact resources with more natural and renewable-based materials such as timber, straw bale, and earth in the construction of building materials. Research and development also focus on increasing the use of recycling materials to replace raw materials such as scrap steel, fly ash to produce building materials. Considering to improve the environmental benefits of material it is necessary to encourage more international collaboration and strengthen the policy aspects to promote the principal to reduce, reuse and recycle to reduce the consumption of virgin raw materials.

Life Cycle Cost Analysis for Green Buildings

IMCS Illankoon, Vivian WY Tam, and Khoa N Le, Western Sydney University, Penrith, NSW, Australia

© 2020 Elsevier Inc. All rights reserved.

Introduction

Green building implementation is one of the most widely discussed topics of this decade. However, green building implementation is strongly associated with higher costs. There are mixed reviews in the literature regarding the initial cost (Richardson and Lynes, 2007). According to Tatari and Kucukvar (2011), Leadership in Energy and Environmental Design (LEED) registered buildings have to pay a cost premium of 0.66% to obtain a certified status, 2.11% for silver status, 4.41% for gold status, and 6.5% for platinum status. Further, Dwaikat and Ali (2016) illustrated that the maximum reported cost premium of a green building reaches up to 21%. However, these studies focused on the initial cost of the green building.

According to Green Building Council of Australia (2013) Green Star certified buildings use 66% less electricity and 51% less potable water than conventional Australian buildings. According to McGraw Hill Construction (2013), in new green buildings, operation costs decrease by more than 8% over a period of one year, while green retrofits exhibit a decrease of 9%. Similarly, Fowler and Rauch (2006) illustrated that certain green buildings consume approximately 26% less energy and demonstrated 13% lower maintenance costs compared to average commercial buildings. These cost savings throughout the life-cycle are not captured in the initial cost calculations. Therefore, Zhang *et al.* (2018), illustrated that the life-cycle perspective is overlooked in green buildings and therefore, there is an urgent need to provide comprehensive and urgent evidence on life-cycle costs.

Green building implementation has become a requirement in the status quo and therefore, the negative influence of initial cost premiums needs to be eradicated from the green building concept. For that purpose, in the initial decision-making stages there should be a model to look into the life-cycle costs of green buildings considering all the life-cycle savings. According to Zuo *et al.* (2017), the uptake of life-cycle cost in construction is rather slow in the Australian context. Therefore, this research aims to analyse the life-cycle cost for green buildings focusing on specific green building requirements.

Life-Cycle Cost Analysis for Green Building Credits

With the development of green buildings, there was a requirement to evaluate the performance of green buildings. According to the World Green Building Council (2018), many countries have their own green building councils. Most of these countries have their own green building rating tools focusing on various key criteria such as water efficiency, energy efficiency land use and so on. According to Lu *et al.* (2017), to pursue sustainable development, appropriate measurements are critical. Further, Asdrubali *et al.* (2015) identified that there are many green building rating tools that have been developed by many countries, all with the aim of reducing environmental impacts in both, construction and management phases of buildings.

Most green buildings rating tools mainly focus on criteria, such as indoor environmental quality (IEQ), energy, water, and operational waste (Building Construction Authority, 2013; Building Research Establishment Environment Assessment Method, 2014; Green Building Council of Australia, 2015; United States Green Building Council, 2014). Most of the benefits of green buildings such as better human conditions, efficiency in energy and water, life-cycle cost savings, and lower negative impact to the environment are derived through the operational phase, with effective operations of these aspects.

Initially, with the rising interest and demand from policy makers to achieve a sustainable society, there had been an increasing interest in environmental assessments of the built environment, focusing on energy use in buildings, the sick building syndrome, indoor climate, building materials containing hazardous substances, and/or many other aspects (Forsberg and Von Malmberg, 2004). Afterwards, separate environmental indicators were developed, such as energy and water efficiency measurements for the needs of relevant interest groups for building ratings (Haapio and Viitaniemi, 2008). However, these individual benchmarks serve to emphasise the need for a comprehensive rating tool to provide a thorough evaluation of building performance against a broad spectrum of environmental criteria (Ding, 2008). However, the first real attempt to establish comprehensive means of simultaneously assessing a broad range of environmental considerations in buildings was the BREEAM (Building Research Establishment Environment Assessment Method, 2015; Crawley and Aho, 1999) rating tool. There had been many green building rating tools developed by many organisations worldwide ever since.

After an extensive study focusing on 71 green building councils worldwide, Illankoon *et al.* (2017), identified eight widely used green building rating tools representing the five main regions worldwide. These widely used rating tools are: LEED, BREEAM, Green Star from Australia, BEAM (Building Environmental Assessment Method) Plus from Hong Kong, CASBEE from Japan, Green Building Index (GBI) from Malaysia, and the Indian Green Building Council Rating (IGBC) from India. Each of these rating tools has different types of schemes, various ratings, and also various key criteria upon which the building is evaluated. Further, according to Illankoon *et al.* (2017), energy, water, IEQ and material are the widely discussed green building requirements by all these widely used green building rating tools.

After analysing all the credits in Green Star Design and As-Built version 1.1, Illankoon *et al.* (2016), illustrated that out of all the credits with a contribution to life-cycle cost, 3% of the credit points were from management key criteria, 22% were from the energy criteria, 8% came from the IEQ criteria, 12% came from both, material and water criteria, 5% were the emission key criteria, and

1% came from land used and ecology key criteria. Therefore, it is evident that the life-cycle cost contribution is significant in criteria such as energy, IEQ, material and water, which perfectly coincides with the widely assessed criteria among green building rating tools. Therefore, this research study focus on these key criteria for life-cycle cost analysis. Further, Green Star Design and As-Built version 1.1 is identified as the guide for green buildings.

Initially, Green Building Council of Australia had Green legacy tools, and by the end of 2015, all these tools were superseded by a new set of green building rating tools. These tools include four green building rating tools, namely, 'Green Star- Design and As Built', 'Green Star - Interiors', 'Green Star - Communities' and 'Green Star - Performance'. Each of these green building rating tools is applied for different sectors in the built environment. Further, in Green Star there is a scale of 6 stars, starting from one star for minimum practice, and six stars for world leadership. Further, Green Star - Design and As-Built, Interiors, and Communities projects can achieve Green Star certifications of 4–6 Stars. Buildings assessed using the Green Star - Performance rating tool can achieve a Green Star rating from 1 to 6 Stars (Green Building Council of Australia, 2013).

In Green Star Design and As-Built v1.1 tool, there are nine environmental categories, namely, management, IEQ, energy, transport, water, materials, emissions, land use and ecology and innovation. These categories are given credits, and the final score is the sum of all the credit points. Final certification is awarded based on the final score.

Research Methodology for Life-Cycle Cost Calculation and Analysis

According to the Australian National Audit Office (2001), the process of life-cycle costing fundamentally involves assessing costs that arise from an asset over its lifespan, and evaluating alternatives that have an impact on this cost of ownership across the five main phases namely, design, purchase and construction, operations, maintenance, and development and disposal (Australian National Audit Office, 2001).

The life-cycle cost calculation follows the ISO 15686-5:2017, namely, 'Building and construction assets – service life planning – Part 5: Life-cycle costing standard' as a guideline (International Organisation for Standardization ISO, 2017). The net present value (NPV) technique is used to calculate life-cycle costs. Eq. (1) shows the formula for the NPV calculation.

$$NPV(i, N) = \sum_{t=0}^N \frac{R_t}{(1+i)^t} \quad (1)$$

where i denotes the discount rate, t denotes the time of cash flow, R_t denotes the net cash flow, and N is the total number of periods.

The discount rate is established considering the time value of money and the associated risk. The minimum attractive rate of return is commonly used as the discount rate (Dell'Isola and Kirk, 2003). The interest rate on a 25-year treasury bond in Australia is 3.25% per annum (Australian Government, 2016). Furthermore, the return on assets for a non-residential construction firm is approximately 3.30% (Deloitte Access Economics, 2016). Therefore, the discount rate is taken as 3.25% for this calculation. However, this rate changes for each user, because the associated risk differs from person to person. Therefore, in order to calculate the life-cycle cost, a user should identify the associated discount rate. Thus, in the life-cycle cost model, the discount rate is a variable input.

According to International Organisation for Standardization (ISO) (2017), life-cycle costing in construction commences from the planning stage and ends with the disposal stage. Therefore, this study follows a 'gate to grave' analysis on life-cycle costs for green office buildings. The time period for this life-cycle cost calculation is 60 years, as required by the Green Building Council of Australia (2015). Further, all the costs are normalised to one square metre of gross floor area (GFA) of the building.

Externalities and social benefits are not considered in life-cycle costs, as these costs fall under whole-life costing, and not life-cycle costing (International Organisation for Standardization ISO, 2017). In this research study, the construction costs are termed as 'initial cost' because these costs are incurred in the initial stages of the life-cycle, and also include management costs related to construction, as well.

All the costs in this research study are collected from the six main central business districts (CBDs) in Australia, namely, Adelaide, Brisbane, Hobart, Melbourne, Perth, and Sydney. All the prices are excluding Goods and Services Tax (GST) and profit. The initial cost is developed based on first principles using current market prices, and includes all the material, labour, and plant costs.

Maintenance requirements are based on maintenance manuals and guidance from maintenance engineers on specific products and materials. The maintenance requirements are further developed based on the detailed analysis provided by Dell'Isola and Kirk (2003), and Stanford (2010). Apart from maintenance, this study considered replacement of different material, as well. As an example, timber flooring requires replacement in 50 years (Dell'Isola and Kirk, 2003). In such a scenario, the timber flooring is replaced in the fiftieth year of the life-cycle and the cost is discounted to the present value, using Eq. (1).

If maintenance occurs annually over the 60 years lifespan of a building, the annual cost should be discounted 60 times. To avoid excessive calculations, the present value of annuity (PVA) for a period of 60 years is calculated using Eq. (2).

$$PVA = R_m \times \left(\frac{1 - (1+i)^{-N}}{i} \right) \quad (2)$$

where i denotes the discount rate, R_m denotes the annual maintenance cost, and N is the total number of periods.

This research study assumes that the building will be demolished at the end of 60 year period. Further, an additional cost is added for the extra care required during demolition, if a particular item is re-used. The debris is assumed to be transported 15 km away from the site. Disposal of these items occur at the end of the life-cycle. The life-cycle cost calculations include all these related costs and discount them to the present value using Eq. (1).

Sensitivity Analysis of Life-Cycle Cost to the Changes in Discount Rates

The life-cycle cost calculation is based on certain variables. The life-cycle cost fluctuates based on changes in the prices of materials. Therefore, it is also necessary to predict the influence of these uncertain variables in the absence of accurate data by using certain techniques, such as sensitivity analysis (Wong *et al.*, 2010). Therefore, a sensitivity analysis is carried out for the changes in discounting rate for each key each criteria.

IEQ Key Criterion

As the name suggests, IEQ refers to the internal environment quality, or, the quality of the environment within the building, especially focusing on the occupants. According to the Green Building Council of Australia (2015), IEQ key criterion aims to encourage and reward initiatives that enhance the comfort and well-being of occupants. Most of the credits included in this key criterion include all the three cost components of the life-cycle cost.

In the IEQ key criterion, credits such as 'IEQ9.1 Ventilation System Attributes', 'IEQ9.2 Provision of Outdoor Air', 'IEQ14.1 Thermal Comfort' and 'IEQ14.2 Advanced Thermal Comfort' have different options to achieve the credit points, depending on the type of ventilation system in use. As an example, if a building is naturally ventilated, the standards and systems considered for that type of ventilation are completely different from those considered for a building with mechanical ventilation. Therefore, while calculating the life-cycle cost, these two types are calculated separately, and these costs have significant differences in their values. Further, there is a dependency on 'W18B.3 Heat Rejection', whose credit points are awarded when there is no water used for heat rejection. Therefore, a mechanically ventilated system is further divided into two, based on the type of heat rejection method in use. Finally, life-cycle cost calculations are carried out for naturally ventilated systems, mechanically ventilated systems using water for heat rejection, and mechanically ventilated systems using air for heat rejection, separately.

Life-Cycle Cost Calculation for IEQ Credits

Life-cycle cost is calculated for each of the credits in the IEQ criterion. The calculation formulae are presented as follows:

$$\begin{aligned} \text{Life - cycle cost for providing air to the building} \\ = \text{Initial cost for providing outdoor air} + (\text{Annual maintenance}) \times \text{PVa} \\ + \text{NPV for cleaning duct work every 5 years} + \text{NPV for replacing ductwork and other components every 25 years} \\ + \text{NPV of cost of demolition} \end{aligned} \quad (3)$$

$$\begin{aligned} \text{Annual maintenance cost} \\ = \text{Nr of hours per session} \times \text{Nr of Air Conditioning mechanics} \times \text{Hourly rate per Air Conditioning mechanic} \end{aligned} \quad (4)$$

$$\begin{aligned} \text{Life - cycle cost for exhaust air ducts} \\ = \text{Initial cost for providing exhaust air duct} \\ + (\text{Nr of hours for annual maintenance} \times \text{Nr of labourers} \times \text{Hourly labour rate}) \times \text{PV} \\ + \text{NPV for cleaning exhaust ducts every 5 years} + \text{NPV of replacement cost after 30 years} \\ + \text{NPV of cost of demolition} \end{aligned} \quad (5)$$

$$\begin{aligned} \text{Life - cycle cost for acoustic comfort} \\ = \text{Consultancy fee for the acoustic consultant} + \text{Initial cost of sound insulation} \\ + \text{NPV for annual maintenance for every 5 years} \end{aligned} \quad (6)$$

$$\begin{aligned} \text{Life - cycle cost for internal lighting} \\ = \text{Initial cost for light fittings, fixtures and lighting points} + (\text{Annual maintenance} \times \text{PVA}) \\ + \text{Replacement cost of lamps every 3 years} + \text{NPV of annual energy saving} \times 0.26 \\ + \text{NPV of cost of demolition} \end{aligned} \quad (7)$$

$$\begin{aligned} \text{Annual maintenance cost} \\ = [(\text{Nr of hours for annual maintenance} \times \text{Nr of labourers} \times \text{Hourly labour rate}) \\ + (\text{Nr of hours for annual maintenance} \times \text{Nr of electricians} \times \text{Hourly rate for Electrician})] \\ + (\text{Nr of hours for monthly visual inspection and cleaning for lighting fixtures and controls} \\ \times \text{Hourly labour rate} \times 12) \end{aligned} \quad (8)$$

$$\begin{aligned} \text{Life – cycle cost for internal blinds} \\ = \text{Initial cost for internal blinds including fixing} \\ + \text{NPV of maintenance cost every 2 years including replacement if required} + \text{NPV of cost of demolition} \end{aligned} \quad (9)$$

$$\text{Life – cycle cost for paints} = \text{Initial cost for painting} + (\text{Annual maintenance}) \times \text{PVA} + \text{NPV for repainting every 7 years} \quad (10)$$

$$\begin{aligned} \text{Life – cycle cost for carpets} \\ = \text{Initial cost for carpets} + \text{NPV of maintenance cost every 2 years} \\ + \text{NPV of replacement cost every 15 years} + \text{NPV of cost of demolition} \end{aligned} \quad (11)$$

$$\begin{aligned} \text{Life – cycle cost for engineered wood products} \\ = \text{Initial cost for interior doors including fixing} + (\text{Annual maintenance cost}) \times \text{PVA} \\ + \text{NPV for demolition} \end{aligned} \quad (12)$$

$$\begin{aligned} \text{Life – cycle cost for thermal comfort} \\ = \text{Initial cost for HVAC system excluding ductwork} + (\text{Annual maintenance} \times \text{PVA}) \\ + \text{Replacement costs every 3 years} + \text{NPV of annual energy saving} \times 0.43 \times + \text{NPV of cost of demolition} \end{aligned} \quad (13)$$

$$\begin{aligned} \text{Annual maintenance cost} \\ = [(\text{Nr of hours for daily inspections} \times \text{Nr of labourers} \times \text{Hourly labour rate}) \times 365] \\ + (\text{Nr of hours for annual maintenance} \times \text{Nr of Air Conditioning technicians} \\ \times \text{Hourly rate for Air Conditioning technician}) \\ + [(\text{Nr of hours for quarterly maintenance} \times \text{Nr of Air Conditioning technicians} \\ \times \text{Hourly rate for Air Conditioning technician} \times 4)] \end{aligned} \quad (14)$$

By following the given formulae, life-cycle cost can be calculated. An example of the life-cycle cost calculation considering a discount rate 3.25% is given in [Table 1](#).

As per Green Star Design and As-Built version 1.1, a building needs to be evaluated by an acoustic consultant to achieve acoustic comfort credits. Therefore, [Eq. \(6\)](#) included consultancy fees for an acoustic consultant. The cost of demolition is not included separately in [Eq. \(6\)](#). The main reason for this is that sound insulation material will be demolished along with the building structure and allocating separately for demolition of sound insulation is not needed, as the cost is very minimal.

In [Eq. \(7\)](#), 6% of energy savings are allocated to the lighting system, because, according to the [Department of Climate Change and Energy Efficiency \(2012\)](#), in Australian commercial office buildings, the lighting system consumes 26% of the total energy consumption. Therefore, energy savings are also apportioned based on the energy consumption of the building. Similarly, in [Eq. \(13\)](#), only 43% of energy savings are considered due to the proportion of energy consumed by the Heating Ventilation Air Conditioning (HVAC) system [Department of Climate Change and Energy Efficiency \(2012\)](#).

Table 1 An example of life-cycle cost for IEQ credits

Discount rate – 3.25% Ventilation type – Mechanically ventilated using water cooled heat rejection

Credits	Credit point	Life-cycle cost (AUD/m ²)					
		Adelaide	Brisbane	Hobart	Melbourne	Perth	Sydney
IEQ 9.1 Ventilation System Attributes	1	15.41	12.89	12.80	15.41	15.65	15.63
IEQ 9.2 Provision of Outdoor Air – Mechanically Ventilated – Water Cooled system	2	124.21	124.38	124.32	124.66	123.83	124.28
IEQ 9.3 Exhaust or Elimination of Pollutants	1	20.76	17.37	17.25	18.93	21.09	21.06
IEQ 10.1 Internal Noise Levels	1	6.05	5.06	5.02	5.51	6.14	6.13
IEQ 10.2 Reverberation	1	7.50	6.27	6.23	6.84	7.62	7.61
IEQ 10.3 Acoustic Separation	1	8.22	6.88	6.83	7.50	8.35	8.34
IEQ 11.0 Minimum Lighting Comfort	Required	45.70	44.45	44.95	42.46	48.44	45.20
IEQ 11.1 General illuminance and glare Reduction	1	60.93	59.27	59.93	56.61	64.58	60.27
IEQ 11.2 Surface Illuminance	1	64.74	62.97	63.68	60.15	68.62	64.03
IEQ 11.3 Localised Lighting Control	1	76.16	74.09	74.92	70.76	80.73	75.33
IEQ 12.0 Glare reduction	Required	33.49	28.01	27.82	30.53	34.02	33.97
IEQ 12.1 Daylight	2	15.63	13.07	12.98	14.25	15.88	15.85

Fig. 1 Sensitivity analysis for IEQ credits at different discount rates.

Sensitivity Analysis for the IEQ Credits

Most of the credits in the IEQ key criterion have significant maintenance costs. Further, certain credits have cost savings throughout the life-cycle of the building. As an example, due to the sufficient light fittings used in the building there are electricity savings. Therefore, this is included in the operational stages of the building. These savings are also reflected in the maintenance, replacement, and other cost components of the life-cycle costs. However, these costs directly depend on the discount rates used in the calculation. Therefore, **Fig. 1** reports the sensitivity analysis of each of these credits, to explain the changes in the discount rate.

Fig. 1 illustrates different life-cycle cost figures for the IEQ credits for an office building located in Sydney with mechanically ventilated air conditioning using water for heat rejection. There are four discount rates used to illustrate the changes in the life-cycle cost (refer **Fig. 1**). There is a reduction in life-cycle cost when the discount rate increases, and this reduction is significant when the contribution of costs during the operational phase is higher in the life-cycle cost calculation. This is significantly evident in credits relating to the lighting system of a building. As an example, credits such as 'IEQ11.0 Minimum Lighting Comfort', 'IEQ11.1 General Illuminance and glare Reduction' and 'IEQ11.2 Surface Illuminance' have significant maintenance, replacement, and other cost proportions. Further, they have considerable costs for electricity throughout the life-cycle of the building. Therefore, with the changes in the discount rates, the changes in the life-cycle cost are significantly evident. However, credits such as 'IEQ10.1 Internal Noise Levels', 'IEQ10.2 Reverberation' and 'IEQ10.3 Acoustic Separation' have minimum costs during the operational phases. Therefore, the maintenance, replacement, and other cost component is at a minimum, and thus, changes to the discount rate are also minimum (refer **Fig. 1**).

The sensitivity of the life-cycle cost to the changes in discount rate is significant in certain IEQ credits. As an example, if 'IEQ12.0 Glare reduction' and 'IEQ11.2 Surface Illuminance' credits are considered when the discount rate is 3%, there is significant difference in the life-cycle costs among these two credits (refer to **Fig. 1**). However, if the discount rate is 12%, there is a slight difference between the two credits (refer to **Fig. 1**). This shows the importance of using the most suited and applicable discount rates to achieve an accurate and consistent life-cycle cost for various requirements. This sensitivity analysis further illustrates that most of the IEQ credits are sensitive to the changes in the discount rate.

Energy Key Criterion

The main aim of the energy key criterion is to reward projects that are designed and constructed to reduce their overall operational energy consumption to below that of a comparable standard-practice building (Green Building Council of Australia, 2015). All the credits in the energy criterion make significant contributions to costs that are incurred during the operational phase of the building. There are five credit elements that have been separately illustrated to achieve 'E15A GHG Emissions Reduction – Prescriptive Pathway'.

These credit elements included building envelopes, glazing, lighting, ventilation and air conditioning, and domestic hot water systems. The building envelope credit focused on roof, floor, and wall insulation, according to the given conditions. There are many options available for these requirements, and considering the optimum solution, focusing on higher thermal resistance and lower life-cycle cost, researchers selected the best material for calculations (Illankoon *et al.*, 2018). Apart from that, glazing, lighting, and air conditioning elements need to fulfil specific requirements. The domestic hot water system needs to be powered by a renewable energy source. Therefore, this credit is bundled with the other credit, namely, 'E16A Prescriptive Pathway: On-site Energy Generation'.

The 'E16A Prescriptive Pathway: On-site Energy Generation' credit requires photovoltaic panels (PV panels) as renewable on-site energy generation sources. Due to the incentives and other benefits given to energy generation through PV panels, there are considerable changes in the life-cycle costs among different CBDs. However, in all the CBDs, there were reported savings in the life-cycle costs (Tam *et al.*, 2017).

Life-Cycle Cost for Energy Credits

Life-cycle cost calculations for energy credits included many formulae as given below.

$$\begin{aligned} \text{Life - cycle cost for building envelope} \\ = \text{Initial cost for building envelope including insulation} + \text{Maintenance cost} \\ + \text{NPV of cost of demolition} \end{aligned} \quad (15)$$

$$\text{Maintenance cost} = \text{NPV of (Nr of hours for maintenance per square meter every 10 years} \times \text{Hourly labour rate)} \quad (16)$$

$$\begin{aligned} \text{Life - cycle cost for glazing} \\ = \text{Initial cost for glazing} \\ + (\text{Nr of hours for annual maintenance} \times \text{Nr of labourers} \times \text{Hourly labour rate}) \times \text{PVA} \\ + \text{NPV of replacement cost} + \text{NPV of cost of demolition} \end{aligned} \quad (17)$$

$$\begin{aligned} \text{Life - cycle cost for domestic hot water (DHW) system} \\ = \text{Initial cost of DHW system} \\ + \text{NPV for maintenance for every 5 years} + \text{NPV for annual energy saving} \\ + \text{NPV of cost of demolition} \end{aligned} \quad (18)$$

$$\begin{aligned} \text{Life - cycle cost for PV panels} \\ = \text{Initial cost for PV panels including fixing} \\ + (\text{Nr of hours of annual maintenance} \times \text{Hourly rate for technicians}) \times \text{PVA} \\ + \text{NPV of cost of demolition} \end{aligned} \quad (19)$$

An example of the life-cycle cost calculation for Sydney considering a discount rate 3.25% is given in Table 2.

According to Green Star there are five options available to achieve 'E15GHG Emissions Reduction'. Further, while using PV panels for on-site energy generation, there are savings on the life-cycle costs.

Sensitivity Analysis for Energy Credits

Similar to the IEQ credits, energy credits also have maintenance, disposal, replacement, and other cost components in the life-cycle cost calculation. Therefore, Fig. 2 illustrates the sensitivity to the life-cycle cost and its impact on the discount rate. The life-cycle costs are for an office building in Sydney and the discount rate changes from 3%, to 5%, to 8%, and to 12%.

Table 2 An example of life-cycle cost for energy credits

Discount rate – 3.25%							
Credits	Credit point	Life-cycle cost (AUD/m ²)					
		Adelaide	Brisbane	Hobart	Melbourne	Perth	Sydney
E15A GHG Emissions Reduction – Building Envelope	1	103.81	114.41	115.85	109.96	119.62	108.68
E15A GHG Emissions Reduction – Glazing	1	146.77	144.37	141.57	141.57	146.77	146.77
E15A GHG Emissions Reduction – Lighting	1	76.16	74.09	74.92	70.76	80.73	75.33
E15A GHG Emissions Reduction – Mechanically Ventilated – Air Cooled System	1	105.27	103.54	104.23	100.78	109.07	104.58
E15A GHG Emissions Reduction – Mechanically Ventilated – Water Cooled System	1	93.16	93.29	93.24	93.50	92.87	93.21
E15A GHG Emissions Reduction – Naturally Ventilated	1	1.46	1.20	1.18	1.30	1.56	1.48
E15A GHG Emissions Reduction – Domestic Hot Water System	1	16.85	17.74	17.38	19.16	14.40	17.21
E16A Prescriptive Pathway: On-site Energy Generation	1	– 18.05	– 15.09	– 14.93	– 16.41	– 18.28	– 18.26

Fig. 2 Sensitivity analysis for energy credits at different discount rates.

According to Fig. 2, there is a major impact on the life-cycle cost, especially for 'E16A Prescriptive Pathway: On-site Energy Generation'. For lower discount rates, there is a cost saving for using the PV panels for energy generation. However, the cost saving is cancelled if the discount rate is higher. Further, a majority of other credits also have substantial impacts on discount rate, and thus, on the life-cycle cost. Therefore, similar to the IEQ criterion, while calculating life-cycle cost, users need to be cautious and input the most suited discount rate to reflect the risk and cost of capital.

Water Key Criterion

By using the prescriptive pathway, the proposed model can achieve up to six credit points through the water key criterion. The main aim of this key criterion is to minimise potable water consumption (Green Building Council of Australia, 2015). To achieve this aim, the users can use water efficient sanitary fixtures, reuse rainwater, avoid using water for heat rejection in HVAC systems, use water efficient landscape irrigation, and so on.

All the credits in water criterion make contributions to all the three types of life-cycle costs. For 'W18B.1 Prescriptive Pathway: Sanitary Fixture Efficiency' credit calculations, all the fixtures are water efficient, and within the required rating levels. Further, while calculating the water costs within the life-cycle of the building, the water savings predicted from using water efficient sanitary fixtures are considered.

Life-Cycle Cost Calculations for Water Credits

While calculating life-cycle costs for 'W18B.2 Prescriptive Pathway: Rainwater Reuse', a 75 kilo-litre water tank is considered. Further, for 'W18B.4 Prescriptive Pathway: Landscape Irrigation' a drip irrigation system is considered. Further, the following formulae were used for calculating the life-cycle cost for water credits.

$$\begin{aligned}
 &\text{Life - cycle cost for sanitary fixtures} \\
 &= \text{Initial cost for sanitary fixtures including fixing} \\
 &\quad + \text{Annual maintenance cost} \times \text{PVA} \\
 &\quad - \text{annual water savings from fixtures} \times \text{PVA} \\
 &\quad + \text{NPV of cost of demolition}
 \end{aligned} \tag{20}$$

Life – cycle cost for rainwater tank

$$\begin{aligned}
 &= \text{Initial cost for rainwater tank} \\
 &+ (\text{Nr of hours for annual cleaning} \\
 &\times \text{Nr of labourers} \times \text{Hourly labour rate}) \\
 &\times \text{PVA} - \text{Annual water savings} \\
 &+ \text{NPV of cost of demolition}
 \end{aligned} \tag{21}$$

Life – cycle cost for drip irrigation system

$$\begin{aligned}
 &= \text{Initial cost of drip irrigation system} \\
 &+ (\text{Annual maintenance cost} \times \text{PVA}) \\
 &+ \text{NPV of cost of demolition}
 \end{aligned} \tag{22}$$

All the sanitary fixtures follow the required water efficiency labelling system (WELS). Therefore, the water savings are based on the saving rates given by WELS. After considering these formulae, the life-cycle cost is calculated and reported in [Table 3](#).

According to [Table 3](#), depending on the type of ventilation system in the building, there are two options available for 'W18B.3 Heat Rejection'. However, once again, using natural ventilation is considered to have lesser life-cycle cost.

Sensitivity Analysis for Water Credits

The credits in the water key criterion have an impact on all the different components of life-cycle costs. Therefore, it is worth identifying the sensitivity of these costs to the discount rate. [Fig. 3](#) below reports the sensitivity of the life-cycle costs to the changes in the discount rate.

In [Fig. 3](#), to achieve 'W18B.3 Prescriptive Pathway: Heat Rejection', a HVAC system using air for heat rejection is used. This system incurs regular maintenance, replacement, and demolition costs. Therefore, there are lots of costs depending on the discount rate. This leads to a drastic change in life-cycle cost as a result of the changes in discount rate. 'W18B.2 Prescriptive Pathway: Rainwater Reuse' and 'W18B.4 Prescriptive Pathway: Landscape Irrigation' credits can be achieved using a minimum life-cycle cost, when compared to the other credits in the water key criterion.

Table 3 An example of life-cycle cost for water credits

Credits	Credit point	Life-cycle cost (AUD/m ²)					
		Adelaide	Brisbane	Hobart	Melbourne	Perth	Sydney
W18B.1 Sanitary Fixture Efficiency	1	84.96	71.06	70.29	77.24	86.04	85.97
W18B.2 Rainwater Reuse	1	2.90	2.42	2.40	2.63	2.94	2.93
W18B.3 Heat Rejection – Naturally Ventilated	2	2.90	1.46	1.16	4.90	9.69	9.63
W18B.3 Heat Rejection – Mechanically Ventilated – Air Cooled System	2	147.38	144.96	145.93	141.09	152.70	146.41
W18B.4 Landscape Irrigation	1	0.62	0.52	0.51	0.56	0.63	0.63
W18B.5 Fire System Test Water	1	42.10	41.60	41.50	41.50	50.90	42.70

Fig. 3 Sensitivity analysis for water credits at different discount rates.

Table 4 An example of life-cycle cost for material credits

Credits	Credit point	Life-cycle cost (AUD/m ²)					
		Adelaide	Brisbane	Hobart	Melbourne	Perth	Sydney
Mat 19B.1 Life-Cycle Impacts – Concrete	3	246.10	205.83	201.36	223.73	219.21	214.01
Mat 19B.2B Reduced Use of Steel Reinforcement	2	37.85	40.70	37.31	41.00	43.10	51.05
Mat 20.1 Structural reinforcing Steel	1	1.46	1.20	1.18	1.30	1.56	1.48
Mat 20.2 Timber Products	1	21.30	17.81	17.62	19.36	21.57	21.55
Mat 20.3 Permanent, Formwork, Pipes, Flooring, Blinds and Cables	1	1.46	1.20	1.18	1.30	1.56	1.48
Mat 21 Product Transparency and Sustainability	3	4.39	3.59	3.55	3.90	4.68	4.44
Mat 22A Reduction of Construction And Demolition Waste	1	27.29	27.31	14.21	15.61	30.87	−9.95

The sensitivity to the discount rate is significantly displayed in [Fig. 3](#). As an example, if the discount rate is 3%, out of ‘W18B.1 Prescriptive Pathway: Sanitary Fixture Efficiency’ and ‘W18B.3 Prescriptive Pathway: Heat Rejection’, using water efficient sanitary fixtures credit is clearly cheaper, as per the life-cycle cost (refer to [Fig. 3](#)). However, if the discount rate is 12%, ‘W18B.3 Prescriptive Pathway: Heat Rejection’ is slightly cheaper than it was in the previous scenario. Therefore, this scenario illustrates the importance of using the best suited discount rate for life-cycle cost calculations.

Material Key Criterion

As the name suggests, this key criterion focuses on building materials. According to the [Green Building Council of Australia \(2015\)](#), the aim of this key criterion is to address the consumption of resources in a building construction context, by encouraging the selection of lower impact material. The main focus of this key criterion is on material, namely, concrete, steel, timber, and the minimum use of PVC.

According to [Mori and Ellingwood \(1993\)](#), the long-term strength of concrete changes due to maturity. Further environmental stressors may attack the integrity of concrete and/or steel reinforcement in concrete with or independent of operating, environmental, and accidental loads ([Mori and Ellingwood, 1993](#)) causing the strength to degrade over time. Therefore, according to [Illankoon et al. \(2018\)](#), it can be argued that concrete only needs to be maintained due to certain external issues, such as accidental loads and severe environmental conditions. Further, usually in a building, crack formation is mostly due to design failures or technical failures in placing and curing concrete, and other than that, in normal conditions, specific maintenance is not required for concrete ([Illankoon et al., 2018](#)). Therefore, while using supplementary cementitious material (SCM) in concrete for obtaining ‘Mat19B Prescriptive Pathway – Life cycle Impacts’ maintenance and replacement costs are not included. A similar argument can be used for ‘Mat 20.1 Structural Reinforcing Steel’ as well. Since the building is a concrete framed building, for this credit, only reinforcement steel in concrete is considered. Therefore, there will only be an initial cost and a demolition cost, except in extreme conditions, where the structure needs major renovation. As a result, ‘Mat 20.1 Structural Reinforcing Steel’ credit does not include any maintenance, replacement, and other costs.

There are many SCM materials that can be used. However, according to [Illankoon et al. \(2018\)](#) 50% of cement replaced with slag is the optimum solution for SCM replacement. Therefore, this option is used for life-cycle calculation in the proposed model. Further, the regular maintenance costs included in ‘Mat 20.2 Timber Products’ and in ‘Mat 20.3 Permanent, Formwork, Pipes, Flooring, Blinds and Cables’ are at a minimum. As a result of this, the maintenance, replacement, and other costs are minimised in this key criterion. Therefore, the impact on life-cycle cost due to the changes in discount rate is at a minimum. Further, there are no specific formulae used for life-cycle cost calculations in this key criterion. [Table 4](#) reports the life-cycle cost for material credits at a 3.25% discount rate.

Various credits are discussed under the materials key criterion. The life-cycle cost and the credit points vary significantly in this key criterion. ‘Mat19B.1 Life Cycle Impacts – Concrete’ has the highest life-cycle cost, but this credit also achieves three credit points. Further, ‘Mat22A Reduction of Construction and Demolition Waste’ creates significant change in the life-cycle cost depending on the CBD (refer to [Table 4](#)).

Conclusions

This research study focused on analysing the life-cycle costs of various criteria in green buildings focusing on Green Star Design and As-Built v1.1 as a guideline. Initially, life-cycle cost is calculated for various options and afterwards, sensitivity analysis is also carried out.

Discount rate is one of the significant parameters in life-cycle costing. Credits with higher life-cycle cost contribute towards the costs incurred in the operational stage of building, and this is significantly impacted by the discount rate. Based on sensitivity analysis, majority credits in key criteria, such as IEQ and energy, have a significant impact on the discount rate.

Naturally ventilated system has the lowest life-cycle cost due to lower maintenance costs and life-cycle savings associated with natural ventilation. Therefore, more passive solutions, such as using natural ventilation and natural daylight, should be considered in green building implementation.

According to life-cycle cost calculations, natural ventilation and acoustic comfort have lower life-cycle costs in IEQ criterion. Unless there are user constraints, use of PV panels as a renewable energy generating source in green buildings is a lower life-cycle cost option. However, it is interesting to identify whether these options are considered in green building implementation. As an example, natural ventilation is rarely used on certified green buildings. The main reason for this is the lack of information on life-cycle perspectives in the initial decision-making stages. These can be eliminated by using life-cycle cost approach in the initial decision-making stages.

Passive solutions, such as natural ventilation and rainwater re-use in green buildings derive multiple benefits. As an example, if natural ventilation is used credits such as 'W18B.3 Heat Rejection' is directly achievable. Most of the decisions on material selection are carried out in the initial decision making stages. Therefore, life-cycle cost approach must be considered in the initial decision making stages to gain fruitful benefits.

Recommendations

Based on the conclusions, it is evident that certain credits with lower life-cycle costs are eliminated due to higher initial costs during the initial decision-making stages. Therefore, this study clearly signifies the importance of looking into life-cycle cost perspective, while deciding on the green building implementation within the initial decision-making stages.

Discount rate used to calculate the life-cycle cost has significant importance. It directly influences the selections based on life-cycle cost. Therefore, when carrying out life-cycle cost calculations users should be more careful and accurate in deciding the discount rate.

To obtain the credits representing the material criteria, the suppliers also should be selected properly. Specialist contractors providing the HVAC and electrical systems must also be aware of the perceived green building certification. Therefore, in summary, the green building implementation should be a process that involves various professionals attached to various stages of the building's life-cycle. As a result, this study recommends looking into green building implementation as a whole process, integrating all these requirements.

According to the life-cycle cost calculations, passive solutions, such as using natural ventilation, daylight in buildings, and rainwater tanks are always identified as lower life-cycle solutions. However, provisions such as natural ventilation are rarely used in green buildings. Therefore, it is recommended to consider these passive solutions in green building implementation.

Introduction

The PD are metal frameworks designed to retain artificial replacement teeth in the oral cavity and smaller version is the fixed partial denture (FPD), also known as a fixed bridge, which can be used if normally healthy teeth are present adjacent to the space where the tooth or teeth have been lost (Eggbeer *et al.*, 2005; Campbell *et al.*, 2017; Block, 2017). Human race is using PD or complete dentures (CD) as early as the 7th century BC. It has been reported that in Italy, PD out of human/animal teeth were fastened with gold bands (Donaldson, 1980). The use of wood based CD has been reported in early 16th century in Japan (Anderson *et al.*, 2004). Pierre Fauchard outlined the fabrication of PD/CD using a frame and teeth sculpted from animal bone in 1728. Further in 1820 'Samuel Stockton' prepared high-quality porcelain PD/CD mounted on 18-carat gold plates (Moriyama and Hasegawa, 1987). Later in 1850s PD/CD were made of vulcanite, (a form of hardened rubber) into which porcelain teeth were set (Rueggeberg, 2002). Further, in 1980s technology was developed to construct PD/CD, which is permanently anchored to the bones in the jaw (Hacking and Khademhosseini, 2009). In the 20th century, thermoplastics were used with conventional methods (McCord, 2009). The PD/CD is fixed or removable replacements for teeth. A CD is made to re-establish both the teeth and the hidden bone when all the teeth are missing in an arch (Mijiritsky and Karas, 2004; Sailer *et al.*, 2007).

The PD is secured to the adjacent teeth by attachment to crowns, or caps, that are affixed to the healthy teeth (Canallatos, 2017). There are two main categories of dentures, the distinction being whether they were used to replace missing teeth on the mandibular arch or on the maxillary arch (Esposito *et al.*, 2009; Carr and Brown, 2010).

Dental implants are the latest tooth-replacement technology (Block, 2017). Modern technology has offered significant advances in the materials used to make artificial teeth and enhanced strategies for pinning them in the mouth (Anusavice *et al.*, 2013). There are many different denture designs available, based upon patient specific needs (Ginsburg *et al.*, 2017; Hunter and Light, 2017). Better design for PD/CD provides more agreeable and effective chewing. However, new dentures known as dental implants are prepared by specialized dentists called denturists (Raskin, 2015). The production of metallic restorations in the dental laboratory has conventionally been carried out by the lost wax casting also called investment casting technique (Pompa *et al.*, 2015; Kalavathi *et al.*, 2016). The PD formed by the traditional method is profoundly relied on the skill and experience of the technician. Its superiority is depended on the accuracy of the technician's final judgment (Noort, 2013). The current fabrication (with CM techniques) of denture, bridges, or crowns requires intensified manual work that undergoes number of steps (Dean, 2015). Most importantly, it does not preserve any quantitative information for future retrieval (Chang *et al.*, 2006).

However, PD can be annoying and problematic, and they often provide patients with only a fraction of the chewing force of natural teeth (Seferli *et al.*, 2014). The first efforts to automate the creation of dental restorations started more than 20 years ago (Sokovic and Kopac, 2006; Bagci, 2009). Advanced imaging and CAD/CAM technologies and their applications in enhancing treatment outcomes in implant dentistry have gained widespread interest (Kattadiyil *et al.*, 2014; Anderson *et al.*, 2014). The process of capturing the shapes of objects through surface data sampling and generating a 3D CAD model is termed as reverse engineering (RE) because the process is the reverse of the normal design and manufacturing sequence (Bi and Wang, 2010; Geng and Bidanda, 2017). The early computer-aided design/computer-aided manufacturing (CAD/CAM) systems were relied exclusively on subtractive methods (Liaw and Guvendiren, 2017). The CAD/CAM systems have many advantages in reducing production and labor cost (Farjood *et al.*, 2017). However, AM strategies have demonstrated fruitful in other dental applications, the absence of appropriate design software has constrained their application in producing PD/CD frameworks (Litjens *et al.*, 2017). AM have been exploited to build complex 3D models in medicine since the 1990s (Huettnier *et al.*, 2018). In recent years, AM progressed rapidly in various fields of dentistry as they have the potential to intimidate known drawbacks of subtractive techniques such as fit problems (Milewski, 2017). AM has recently proposed successful applications in various dental fields, such as fabrication of implant surgical guides, frameworks for fixed and removable partial dentures, wax patterns for the dental prosthesis, zirconia prosthesis and molds for metal castings, and maxillofacial prosthesis and finally, complete dentures (Quadri *et al.*, 2017; Azari and Nikzad, 2009; Torabi *et al.*, 2015). Previous studies have established a valid approach to the computer-aided surveying of digital casts, framework design and the subsequent production of sacrificial patterns by using AM technologies (Eggbeer *et al.*, 2006). Some of the commercially available AM techniques are digital light projection (DLP), jet (PolyJet/ProJet) printing, and direct laser metal sintering (DLMS)/selective laser sintering (SLS), FDM (Masood, 1996; Bilgin *et al.*, 2016; Alharbi *et al.*, 2016).

PD or bridge more often consists of replacement teeth attached to a pink or gum-colored plastic base, which is mainly connected by metal framework that holds the denture in place in the mouth (Brehm, 2018; Caron *et al.*, 2018). PD is used when one or more natural teeth remain in the upper or lower jaw (Groot, 2018). A fixed bridge exchanges one or more teeth by insertion crowns on the teeth on either side of the space and attaching artificial teeth to them (Rubbert and Ellermeier, 2018; Muris and

Kleverlaan, 2018). This “bridge” is then cemented into place. Not only does a PD fill in the spaces created by missing teeth, it prevents other teeth from changing position (Rupp *et al.*, 2018). A precision PD is removable and has internal attachments rather than clasps that attach to the adjacent crowns (Lazareva *et al.*, 2018; Longurova *et al.*, 2018).

There are two types of dentures, removable and complete.

Removable PD: Removable PD are for patients who are missing some of their teeth on a particular arch (Wallace *et al.*, 2018). Fixed PD, also known as “crown and bridge” dentures, are made from crowns that are fitted on the remaining teeth (Campbell *et al.*, 2017). They act as abutments and pontics and are made from materials resembling the missing teeth (Kenna *et al.*, 2015; Schimmel *et al.*, 2015). Fixed bridges are more expensive than removable appliances but are more stable (Armellini and Von Fraunhofer, 2004; Bilt, 2011).

Complete dentures: Complete dentures are worn by patients who are missing all of the teeth in a single arch (i.e., the maxillary (upper) or mandibular (lower) arch) (Jepson *et al.*, 2003; Yagi *et al.*, 2017).

Comparison Between CM and AM

CM and AM both are used to prepare parts of different sizes and complexity. However, in CM route more waste is generated as compared to the AM. This is because of the fact that CM is labor intensive and requires high level of technical skill. AM, on the other hand, is a layer by layer process which leaves relatively less waste material, hence also sometimes, called as near zero waste manufacturing. Further versatility of AM process is of no match with CM, (where there is no or very less control on output parameters in CM and AM delivers the product in high dimensional accuracy with good surface finish without much technical skill). Further there are less chances of metal shrinkage in AM. The whole part is prepared under digitalized environment as it is fully controlled. Fig. 1 shows flow chart for preparation of PD with CM and AM technique.

Conventional Manufacturing (CM) for PD Preparation

According to the 8th edition of The Glossary of Prosthodontics Terms, “impression” is defined as “a negative likeness or copy in reverse of the surface of an object; an imprint of the teeth and adjacent structures for use in dentistry” (The glossary of

Fig. 1 Flow chart for preparation of PD.

prosthodontic terms, 2005). The exactness of the impression relies upon the impression materials, tray types and techniques (Ender and Mehl, 2013). Each phase in the process introduces human as well as material error (Nedelcu *et al.*, 2017).

There is some variability in impressions and the resulting master casts, depending on the technique and material used by the operator (Lima *et al.*, 2018). The accuracy of master casts has been the subject of numerous research projects, and is dependent on numerous items, including the water/powder ratio, vacuum versus hand mixing and the type of dental stone and its compatibility with impression materials (Menini *et al.*, 2018; Park and Shin, 2018). Fig. 2 shows 3D view of PD.

Steps for Preparation of PD

In this work, dental crown as shown in Fig. 2 has been selected as the benchmark component. This research work has been divided into 12 stages/steps formally from the benchmark to final cast as shown in Fig. 3. First of all, manufacturing process begins with a preliminary impression of the patient's teeth (stage 1). This impression was used to prepare a diagnostic cast. Once an appropriate preliminary cast/impression has been obtained, the final cast (teeth mold) is made from gypsum, a stone-like product (stage 2). For mixing of investment (mixture of siladent powder and water) three different pH value of water (pH-3, pH-7, pH-10) with different powder/water (P/W) ratios by weight (100/12, 100/15, 100/18) has been used (see Table 1). After this preparation of wax pattern and shaping was done manually with conventional method (stage 3). Therefore, tree formation of wax pattern was done prior to filling the investment in the crucible (stage 4). After this, investment was poured in crucible and around the pattern tree (stage 5–7). Investment was baked in Muffle furnace for 1.5 h at 900°C (stage 8–9). The induction casting setup was used for casting of denture with Ni-Cr based alloy (stage 10–11). The final casting of denture fitted on the mold is available after solidification (stage 12).

Optimization of Input Parameters

Table 1 shows input parameters selected for experimentation. All specimens were casted with different input parameters namely P/W ratio (100/12, 100/15, 100/18), second is pH value of water (pH-3, pH-7, pH-10) and Ni% (62%, 65%, 70%) in Ni-Cr alloy for final casting of PD. The dimensional deviation (Δd value) for one critical dimension 10.70 mm is shown in Fig. 2.

Taguchi L9 orthogonal array based design of experiment has been used for PD preparation (Table 2). It has been observed that PD casted at optimum values of P/W ratio 100/12, pH-7 value of water with 65% of Ni in NiCr alloy gives better results for dimensional accuracy as compared to other parts. The measurements of average Δd on castings were measured on the co-ordinate measuring machine (CMM). The average Δd is the difference in drawing dimension and dimension of finally cast component. Three repetitions have been made to reduce the experimental error.

Fig. 4 shows the main effect plot for mean S/N ratio of various factors of CM process. From Fig. 4, lower variation in dimensional accuracy after casting has been observed for specimen casted with P/W ratio of 100/12, pH-7 value of water with 65% of Ni in NiCr alloy.

Based upon Table 2 and Fig. 4, Table 3 shows the analysis of variance (ANOVA) to understand the percentage contribution of input process parameters.

As observed from Table 3, for controlling the dimensional accuracy in CM route, P/W ratio is the most significant factor followed by Ni% where as pH value is least contributing factor.

Additive Manufacturing (AM) for PD Preparation

AM is a 3D printing process that builds up parts layer by layer and differs greatly from CM techniques (Huang *et al.*, 2013). It uses 3D data on the oral situation of the patient as a basis; this is generated using intraoral scanners or by impression or model scans (Lim *et al.*, 2012; Kruth, 1991).

Fig. 2 3D view of PD.

Fig. 3 Steps involved in making partial denture using CM technique.

AM have been exploited to build complex 3D models in medicine since the 1990s (Frazier, 2014; Pham and Gault, 1998). AM has recently proposed successful applications in various dental fields, such as fabrication of implant surgical guides, (Quadri *et al.*, 2017) frameworks for fixed and removable partial dentures, wax patterns for the dental prosthesis, (Thoma *et al.*, 2017) zirconia prosthesis and molds for metal castings, and maxillofacial prosthesis and finally for complete dentures (AlHelal *et al.*, 2017, 2018).

AM techniques, the so-called “generative manufacturing techniques”, show the possibility to overcome the described shortages (Oilo *et al.*, 2018; Grant *et al.*, 2018). The AM simply consists of two phases: virtual phase (modelling and simulating) (Leitz *et al.*, 2018) and physical phase (fabrication) (Ji *et al.*, 2018). Virtual prototyping is development of model by dynamic and interactive simulation. The course of forming the physical model is formation of 3D physical model by CAD (Lu *et al.*, 2018; Maddox *et al.*, 2018).

Table 1 Input parameters for preparation of PD (with CM and AM)

Input parameters Factor	Symbol	Levels		
P/W ratio (g/ml)	A	1	2	3
pH value of water	B	100/12	100/15	100/18
Ni-Cr alloy (%)	C	pH-3	pH-7	pH-10
		Ni 62	Ni 65	Ni 70
		Ni 62%	Ni 65%	Ni 70%
		Cr 25.6%	Cr 22.5%	Cr 13%
		Si 0.47%	Mo 9.5%	Si 4%
		Co 0.31%		Cu 13%
		Mn 0.03%		
		Mo 11.06%		

Table 2 Observations for PD casting using CM technique

S. no.	P/W ratio	pH value of water	Ni %	Average Δd (mm)	S/N ratio (dB)
1	100/12	pH-3	62%	0.10	20.00
2	100/12	pH-7	65%	0.01	40.00
3	100/12	pH-10	70%	0.09	20.91
4	100/15	pH-3	65%	0.13	17.72
5	100/15	pH-7	70%	0.12	18.41
6	100/15	pH-10	62%	0.15	16.47
7	100/18	pH-3	70%	0.14	17.07
8	100/18	pH-7	62%	0.02	33.97
9	100/18	pH-10	65%	0.11	19.17

**Fig. 4** Main effects plot for mean S/N ratio.

Fused Deposition Modelling (FDM) Technique

The FDM is an AM technique, which extruded a thermoplastic material in the form of layer by layer through a nozzle and controlled by temperature (Azari and Nikzad, 2009; Bourell *et al.*, 2017; Long *et al.*, 2017). The FDM head extrudes and directs the material in ultra-thin layers onto a fixtureless flat base with precision (Vaezi *et al.*, 2018; Adel *et al.*, 2018). The FDM process starts with importing a standard triangulation language (STL) file of a model into pre-processing software (Upcraft and Fletcher, 2003; Nikzad *et al.*, 2011). After reviewing the path data and generating the tool path, the data is downloaded to the FDM machine (Wang *et al.*, 2017; Singh *et al.*, 2017).

Error		1.556

Steps for Preparation of PD

This work has been divided into 12 stages/steps formally from the benchmark to final cast as shown in Fig. 5. First of all, manufacturing process begins with a preliminary impression of the patient's teeth (stage 1). This impression was used to prepare a diagnostic cast. Once an appropriate preliminary cast/impression has been obtained, the final cast (teeth mold) is made from gypsum, a stone-like product (stage 2). For mixing of investment (mixture of siladent powder and water) three different pH value of water was used (pH-3, pH-7, pH-10) with different P/W ratios by weight (100/12, 100/15, 100/18). Then 3D scanning of teeth mold, which is called plaster cast of a patient was digitally scanned with an optical scanner and the captured surface data were imported to 3-D software, which were then used to preprocess the data and design each component of partial denture framework with reference to the scanned digital model. After this operation, the digital model of framework was created, and the data were

saved as standard triangulation language (STL) format for producing a pattern of partial denture with FDM (stage 3–5). Therefore, tree formation of wax pattern was done prior to filling the investment in the crucible. After this investment was poured in crucible and around the pattern tree (stage 6–7). Investment was baked in Muffle furnace for 1.5 h at 900°C (stage 8–9). The induction casting setup was used for casting of denture with Ni-Cr based alloy (stage 10–11). The final casting of denture fitted on the mold is available after solidification (stage 12).

Optimization of Input Parameters

Based upon Table 1, AM route has been followed for preparation of PD (see Table 4). Based upon Table 4, Fig. 6 shows S/N ratio plot for dimensional accuracy (by using minimum the better type case).

As observed from Fig. 6, best settings have been observed for specimen casted with P/W ratio of 100/12, pH-7 value of water with 62% of Ni in Ni-Cr alloy. Further based upon Table 4 and Fig. 6, Table 5 shows percentage contribution of input parameters for Δd via AM route.

As observed from Table 5, for controlling the dimensional accuracy, P/W ratio is the most significant factor. This observation is similar to the case of CM (see Table 3). However the Ni% is least contributing for dimensional accuracy in AM route. This may be because of the high temperature requirement in draining out investment material in AM route. It should be noted that in CM route the de-waxing temperature is in the range of 100–150°C, whereas in AM route this varies from 1050 to 1100°C. The results are in line with the observations made by other investigators (Singh *et al.*, 2017).

Conclusions

In this article detailed procedure for preparation of Ni-Cr based PD by CM and AM technique has been outlined. Two case studies have been presented for CM and AM route for preparation of PD.

- It has been observed that dimensional accuracy required in preparation of PD by both AM and CM lies in acceptable range (as per commercial practice) and best settings for both cases have common with P/W ratio of 100/12, pH-7 value of water. Since CM technique undergoes generous number of steps, hence the procedure takes a long time to finish, whereas, AM technique is more efficient.
- For preparation of PD by CM and AM, P/W ratio is the most significant parameter with percentage contribution of 52.45% and 49.5% respectively. Since the AM route requires high temperature (1050–1100°C) for removal of investment material, the second most significant parameter is pH value with contribution of 41.68%, whereas in CM route the second most significant parameter for dimensional accuracy is Ni%.

Introduction

The term protective coating or surface engineering means modifying or engineering the surface of material to increase protection against wear and corrosion properties along with other properties. Among the processes employed for protective coating, incorporation of ceramic particles to produce composite protective coating or layer by melting is gaining popularity (Maleque *et al.*, 2017). High energy laser cladding (Zhou *et al.*, 2016; Yang *et al.*, 2016; Qunshuang *et al.*, 2017) and electron beam melting technique (Peng *et al.*, 2011; Lienert *et al.*, 1993) are commonly used for processing such composite protective coating which are reported to significantly increase wear and corrosion resistance of engineering component surfaces. Electron beam welding (EBW) for composite surface coating was developed starting in the late of 1950s. In that method, the electrons are accelerated and kinetic energy is used as the heat input for melting of the substrate material. A negatively-charged cathode filament is heated up to its thermionic emission temperature where electrons are generated. The substrate surface is bombarded with the electron beam at 70% of speed of light. The heat comes from approximately 95% of the electron's kinetic energy. The diameters of the electron beam are between 0.3 and 0.8 mm. Due to its high power density, one of the superior abilities of EBW is the capability of deep melting of the surface layer (Sun and Karppi, 1996).

The composite protective coating of materials can be performed by melting process where high energy source is applied to melt the surface of the substrate together with the reinforcing particles (Sathiya *et al.*, 2009; Lailatul and Maleque, 2017). This resulted in a strong metallurgical bonding upon solidification between the reinforcing particles and the substrate material. The melting process is commonly utilized for ceramic particles for reinforcement due to their superior hardness and thermal stability. In other work, the composite coated layer obtained through laser cladding technique showed low porosity, with homogenous microstructure with proper control of thickness by manipulating the process parameters (Fernández *et al.*, 2014).

The reinforcement can be fed onto the surface of the substrate material using either powder blown, wire feed or pre-place powder surfacing method (Fernández *et al.*, 2014; Folkes, 1994). Powder injection or blown method applied a stream of gas which are usually argon, CO₂ or oxygen to carry the reinforcing powders. The reinforcing powders are delivered using coaxial or lateral feed method. The flow of the carrier gas is maintained properly to have uniform distribution of reinforcement and good quality of melt pool layer. The use of higher gas flow rate in this method can easily decrease the melting temperature of the substrate and hence, less dissolution of particles. On the other hand, the flowability of the reinforcing ceramic particles is reduced with the use of lower gas flow rate and hence, fewer amounts of particles reach the melting area.

Wire feed method is an approach where composite protective coating of metallic materials is performed using filler material. The spool containing filler material is directly fed through a nozzle and onto the substrate. To have a good quality of melt structure, the wire feed used to carry the reinforced particulate material should be free from defects which can affect the flow consistency. When the wire used is bent, the filler material could have deviated from reaching the center of the melt pool. According to Kou (2003), this technique does not waste any filler material compared to the powder injection method. However, some extent of reinforced particles may not reach the center of the melt pool at a certain heat input because of the use of slower wire feed rate. The quality of the melt structure is strongly affected by the wire feed rate. Among the composite surface coating methods, particulate preplacement method is the cheapest, and a simple, flexible way of composite protective coating of metallic alloys with good metallurgical bonding and decent melt pool structure (Maleque *et al.*, 2018). A binder solution such as polyvinyl acetate (PVA) is used to preplace the particulate on the substrate material so that the particulate is not blown away by the shielding gases during the melting process. However, the excessive use of binder could lead to porosity that comes from escaped gas during solidification. The particulate preplacement process is followed by the application of high heat energy to melt the surface layer. Upon solidification, the melted reinforced particle together with the melted surface of the substrate can bond and develop a new microstructure with modified physical, mechanical and tribological properties (Adeleke and Maleque, 2014).

Overall, all the composite protective surfacing techniques mentioned earlier such as powder (particulate) blown or injection method, wire feed method and pre-place particulate method have their own mechanism to supply the reinforcing particulate material onto the surface of the substrate during the melting process. Each of the method has its own sensitive parameters that affect the end quality of the produced melt structure. For instance, powder blown technique heavily relies on the gas flow rate for consistency of the feeding of reinforcing particulates. Generally, pre-place particulate method is beneficial compared to the others because it is the cheapest, simple and flexible way with the ability to produce a good melt microstructure.

However, particulate protective coatings using those techniques have a limited application because of the expensive establishment and precision control of the system. An alternative and novel method was developed using conventional melting (surfacing) technique by TIG torch melting for composite protective coating which is suitable for high temperature application as

well. Requirement for high temperature application includes (Idriss *et al.*, 2017): materials should exhibit high hardness combined with lower wear rate, controlled coefficient of friction, higher level of durability and life-time. Therefore, composite protective surfacing with particulate ceramics for composite protective surface is vital. The main aim of this work is to provide an overview on the composite protective coating of engineering materials by melting technique followed by the evaluation of the influence of TIG parameters on the performance characteristics such as microstructural features, surface integrity and microhardness.

Composite Protective Coating by Melting

Composite protective coating guarantees wear resistance protection while the substrate material maintains the mechanical properties and the component geometry (Maleque *et al.*, 2017). This type of surface is formed by incorporating ceramic particles (such as TiC, SiC, WC etc.) into a molten thin and near surface region of substrate using conventional TIG torch welding technique in order to enhance the wear resistance properties and other mechanical properties which in turn prolong the life of the component or structure. Composite protective coating consists of fusion zone (FZ), heat affected zone (HAZ) and substrate or parent metal (PM) zone as shown in Fig. 1.

The benefits of TIG torch technique are:

- Cheaper in establishment,
- Flexible and simple technique,
- Formed hard layer into a molten thin and near surface region of substrates,
- Good metallurgical bonding between hard particles and substrate material,
- Less processing time,
- Provides good control of heat input.

The features of TIG torch melting compared to the other composite protective coating techniques such as electron beam welding (EBW), laser cladding and thermal spraying are shown in Table 1 in a matrix form.

Materials and Methods

Materials

AISI 4340 low alloy steel plate with the dimension of 100 mm × 40 mm × 20 mm was selected as the parent material which was ground using silicon emery paper and thoroughly cleaned in acetone to remove all the contaminants in a form of oxide layer or grease. The chemical composition of the substrate material is shown in Table 2. Titanium carbide (TiC) particulate (99.8% purity) supplied by Sigma Aldrich was used for composite protective coating. The average size of the titanium carbide particles is 10 µm.

The TiC particulates weighed at the proportion of 1.0 mg/mm² was mixed with organic binder (PVA) and preplaced on the dry substrate surface. The pre-coated substrates were then further cured in an oven to remove any moisture before applying composite protective coating under TIG torch melting technique.

Particulate Composite Protective Coating

In order to develop composite protective coating, surface melting was performed using TIG torch welding. A throated tungsten electrode (2.4 mm Ø) was used to generate a stable arc for the melting at a fixed height of 2 mm from the substrate. The energy density of the TIG torch was controlled by the supply of fixed current (80 A) and four different voltage such as 30 V, 35 V, 45 V and 55 V which corresponds to four different heat inputs of 1152 J/mm, 1344 J/mm, 1728 J/mm and 2112 J/mm respectively with the TiC particle feed rate of 1 mg/mm² to produce single track along the width of the substrate. During the melting process, a stream of pure argon gas (gas flow rate of 20 L/min) was supplied to avoid excessive oxidation of the molten pool. Fig. 2 shows the schematic diagram of TIG torch set-up for composite protective coating development.

Fig. 1 Composite protective coating layer consists of fusion zone, HAZ and substrate zone.

Table 1 TIG torch protective surface coating compared to the other surface coating techniques

Parameters	Tungsten inert gas welding	Electron beam welding	Laser cladding	Thermal spraying
Working principle	Heat is generated from an electric arc produced between the tungsten electrode and the metal substrate The inert gas used is usually argon and its function is to control the weld environment and thus preventing contamination and oxidation	A beam of electrons is induced and accelerated to have a high amount of kinetic energy The beam of electrons collides with the substrate material and their kinetic energy is transformed into heat, which lead to melting	Laser cladding is a modern technology whereby another material is fused onto the surface of a substrate The laser beam is aimed at the substrate with a selected spot size. The powder coating material is carried by an inert gas through a powder nozzle into the melt pool	Coating material is heated and deposited as individual particles onto the new surface material The sprayed reinforced particles latch onto the substrate surface, they solidify and build up into laminar structure forming the new coating layers
Merits	No flux required due to the use of inert gas shielding, hence, there is no slag or inclusion High surface quality Easy to operate Low installation and maintenance cost Wide range of materials can be used Small flames or sparks leads to less amount of distortion	Perform in vacuum and hence, there is no gas contamination High surface quality even on thicker materials Stable and repeatable process Superior controlled process leads to less distortion and shrinkage	Highly focused heat source, hence, cladding can be placed precisely Full metallurgical bonding with little void and porosity Highly consistence Wide range of materials High energy efficiency	Highest deposition rates up to 15 kg/h Wide range of coating materials Easy to operate Require low input power Can be used on thermally sensitive substrate such as electronic components since less heat is applied on substrate
Demerits	Low deposition rate Small amount of heat sources and hence not suitable for thicker material Slow process	High installation cost due to vacuum set up Size restricted depends on vacuum chamber X-rays generated during the process	Relatively high cost Highly sensitive process Might produce poor quality weld due to random disturbance in the system	Can only be applied on conductive material in certain wire form Large fumes and dust formed, hence there is health and safety issues Higher porosity and oxide levels compared to other methods

Table 2 Composition of the AISI 4340 steel

Element	C	Si	Mn	S	P	Cr	Ni	Mo	Fe
Composition (Wt%)	0.42	0.16	0.65	0.04	0.035	0.75	1.76	0.24	Bal.

Coating Characterization

After particulate composite protective coating development, specimens for hardness measurement and morphological characterization were cut along the transverse section of the re-solidified tracks. The cross section specimens were prepared using standard metallographic procedure. The specimen surfaces were then etched with a solution of 2%. The surface topography of the melt pool layers were characterized by scanning electron microscope. The microhardness at a depth of 200 μm from the top surface of the coating was measured using Wilson Wolpert Vickers microhardness tester with a 500-gf load and 10-s dwelling time. The test results were calculated based on the average of three indentations from each specimen.

Results and Discussion

Surface Topography

The surface topography in Fig. 3 shows different formation of rippling marks on the surface of the single melt layers from the energy input of 1152 J/mm to 2112 J/mm. The topography surface in general showed completely free from any crack on the

Fig. 2 TIG Torch set-up for composite protective coating.

Fig. 3 Effect of energy input on surface topography of TiC particulate protective layer at: (a) 1152 J/mm, (b) 1344 J/mm, (c) 1728 J/mm, (d) 2112 J/mm. TiC particle feed rate, 1 mg/mm²; working distance, 1 mm; and gas flow rate, 20 lit/min.

surface. The protective coating layer resulted in prominent rippling marks that are perpendicular and along the direction of the TIG torch moving path. However, the single layer that is melted at the lowest heat input of 1152 J/mm shown in [Fig. 3\(a\)](#) does not show obvious ripples as observed in for those with higher energy input. The input energy of 1152 J/mm solidified at shortest period of time preventing from enough convection force to turbulence the melt and this might have contributed to the poor rippling marks in both directions which are perpendicular and parallel to the TIG travelling path.

The higher heat input showed almost evenly distributed and consistent rippling marks formation along and perpendicular to TIG travelling direction indicating that most of the input energy contributed to form less viscous melt layer associated with longer solidification time. Rippling marks were also observed by other researchers in the laser and TIG melting technique caused by freezing of the fluid melt ([Mridha et al., 2012](#); [Maleque et al., 2013](#)).

Microstructure

Microstructure of TiC particulate protective coating on low alloy steel substrate at different heat input energy is shown in [Fig. 4](#). The protective layer showed hemispherical in shape due to the Gaussian energy distribution that is high in arc density in the

Fig. 4 Microstructure of the protective coating layer at different heat input energy: (a) 1152 J/mm, (b) 1344 J/mm, (c) 1728 J/mm and (d) 2112 J/mm. TiC particle feed rate, 1 mg/mm²; working distance, 1 mm; and gas flow rate, 20 lit/min.

Fig. 5 Flower and globular type of TiC particulate composite protective surface at heat input of 1344 J/mm.

middle of the melt and steadily decreases towards both left and right edges. The lower energy input (1152 J/mm) exhibited less melting pool thus allowing for more TiC particulates to remain un-dissolved particularly at the edge of the melted layer.

The existence of very small area of rich TiC re-precipitated region in the middle of melt in **Fig. 4(a)** suggested that the energy fused just below the arc tip may have generated melting temperature of TiC which is slightly above 3230°C thus sufficiently melting small amount of these particulates. The heat input at 1344 J/mm as in **Fig. 4(b)** exhibited improvement in TiC dissolution where agglomeration is likely to be less than lower heat input. However this energy enlarges the rich TiC re-precipitated region that is located near the arc source together with providing homogeneous distribution of un-dissolved and partially dissolved TiC particulates embedded in the melt layer. Increasing the melting efficiency by increasing heat input to 1728 J/mm and 2112 J/mm (as shown in **Fig. 4(c)** and **(d)**) resulted in dominance of TiC particulates dissolution together with increased melt pool geometry. This is an apparent sign that high in substrate dilution had occurred to help surging the particles along melt waves in the presence of Marangonian convection force.

The cross sectional micrograph of the protective coating under the heat input of 1344 J/mm showed re-precipitation of TiC in globular and flower type of microstructures as shown in **Fig. 5**. The formation of this type of microstructure was also found by other researchers (*Idriss et al., 2017*). Although the energy is considered to be high at the energy input of 1728 J/mm and 2112 J/mm, lower

Fig. 6 EDX result of the re-precipitated TiC iron the protective coating surface.

Fig. 7 Microhardness profile of particulate composite protective coating surface of low alloy steel at different heat input energy. TiC particle feed rate, 1 mg/mm²; working distance, 1 mm; and gas flow rate, 20 lit/min.

in TiC agglomeration due to the poor melting efficiency near the substrate remained than those melted with the energy of 1344 J/mm having more in agglomerations. This melt is less viscous on the upper region near the arc source where the energy within this area is sufficient to dissolve the TiC particulates, thus, allows for the re-precipitation of those globular and flower type of TiC microstructures in the presence of longer solidification time.

The EDX results on the re-precipitated TiC microstructure is shown in Fig. 6. The elements of titanium and carbon in Fig. 6 are higher exhibited a little amount of titanium that is observed in the low temperature matrix solution within the re-solidified melt layer at the energy of 1344 J/mm. This is clear evidence that dissolution of TiC happened in the melt layer followed by dissociation of elements into titanium and carbon and the remaining titanium that has not formed TiC remained as solid solution in the matrix.

Microhardness

The microhardness profile of the 1 mg/mm² preplaced particle content on the surface of low alloy steel at different heat input ranging from 1152 J/mm (30 V) to 2112 J/mm (55 V) is presented in Fig. 7. The incorporation of TiC particulates for composite coating layer in general showed improvement in microhardness properties up to 4 times higher than the substrate material. The heat affected zone profile corresponds to the microhardness value ranging from 500 Hv to almost 700 Hv while the substrate at an average of 300 Hv. Melting at different heat inputs showed variation of microhardness values at different depth level which is related to the TiC population, type and amount of substrate dilution from the substrate.

At 30 V power which corresponds to the heat input of 1152 J/mm exhibited gradual decrement from 1000 Hv at the depth of 500 μm to 700 Hv at lower depth level of 1000 μm. This lower energy input showed the lowest microhardness profile on coating layer compared to other heat input. The main reason is the incomplete melting due to the thicker solution that solidify in the presence of defects and poor adhesion or metallurgical bonding of TiC with the lower temperature low alloy steel matrix. Wang *et al.* (2006) also explained that incomplete melting of preplaced particles and cracks are the reason for the reduction of microhardness values. The microhardness trend increasing the depth level acts reversely for 35 V power (energy input of 1344 J/mm) compared to 30 V power (1152 J/mm). Instead of hardness decrement with the increasing depth level, the value is seen to be increased to the lower depth of the melt pool. The microhardness value was more than 1000 Hv at the depth of 400, 500 and 700 μm when measured from the top surface. The main reason of such trend and higher in the hardness value at 35 V power (1344 J/mm) is due to the homogeneous distribution of TiC microstructure consisting of re-precipitated TiC and partial un-dissolved particulates.

The protective coating layer that is produced using the energy input of 1728 J/mm (45 V power) and 2112 J/mm (55 V power) generally showed reduction trend in microhardness along the non-steep hardness profile of the track compared to the lower energy input. The dilution melting of the substrate at 1728 J/mm and 2112 J/mm are coupled with higher dissolution of TiC microstructure that are re-precipitated over larger volume of matrix are the reason for microhardness decrement in the layer. Since TiC has the hardness values at 3000 Hv, incorporation of this particulate promotes the increasing in hardness compared to the substrate material. However, at the depth of 400 μm, the 2112 J/mm heat energy produces microhardness value at 1102 Hv. The 1728 J/mm heat input in TIG melting on the protective coating of alloy steel exhibited the microhardness value at lowest with the value of 800 Hv at 200 μm depth level.

Conclusions

The particulate composite protective coating has been successfully developed on the surface of low alloy steel substrate using conventional TIG torch melting approach. All melted layers exhibited crack free surface together with the cross sectional area which had proven that TiC particulates protective coating via TIG melting endowed superior in adherence compatibility with the AISI 4340 low alloy steel substrate.

In general, rippling marks is an evidence that high dilution of substrate and dissolution of TiC particulates along with more TiC re-precipitation took place beneath the melt surface layer while the dull and undulated ones are indications that undissolved TiC particulates dominated in the embedment of the melt pool. All re-solidified protective coating layer have shown semi hemispherical in shape viewed from the cross sectional side caused by the Gaussian energy distribution from the TIG arc source that depicts greater in arc energy intensity in the middle and gradually depletes as it moves towards the edges. The higher heat input melts more TiC particulates that endowed near to the arc region enriched with re-precipitated TiC that was primarily observed to consist of flower and globular type of microstructures within the matrix. The microstructure contains elements of Ti and C where the evidence can be seen from the EDX result while the matrix showed more in Fe content than the Ti which has been caused by the dissociation of TiC particulates upon melting.

The incorporation of TiC particulates on the surface of the low alloy steel substrate increases hardness properties of the coating layer up to 4 times higher than the substrate that has microhardness value at about 300 Hv. This revealed the potential application of TIG torch melting technique for the composite coatings with the formation of hard composite coating layer in metallic materials especially for high temperature applications.

Introduction

Today polymers are one of the most important materials in daily life because of their tremendous applications. Some of the applications of polymers are in coating, packaging materials, fabrication of composites, biomedical devices, and electronic devices etc. (Singh *et al.*, 2017, 2018a,b). In last two decades, many researchers are trying to use polymers in the field of biomedical applications. The selection of thermoplastics in biomedical applications is mainly based upon its biocompatibility (Gibson *et al.*, 2015; Gress and Kalafsky, 2015). Biocompatibility term is used to describe the suitability of a polymer for exposure to the body or body fluids. Most of the polymers are commercially sold in the form of granules. For fabricating or manufacturing of biomedical devices, scaffolds, functional prototypes some bioactive and biocompatible materials are required be added (DOE, 2015).

HAp is highly in demand as biocompatible materials for the regeneration and reconstruction of bone tissues (Boisvert and Adelstein, 2015). It has all the characteristic features of biocompatible materials (metals, polymers and composites), such as osteo-conductive, non-immunogenic, bioactive, non-toxic and non-inflammatory properties (Chhaya *et al.*, 2015; Xu *et al.*, 2017). In human body, HAp represents 65%–75% in weight of bone and 88%–92% in weight of enamel. Nano-HAp has a strong capacity to bond with proteins (Huang and Leu, 2014). It has significant effects on dental/dental enamel in terms of regeneration and preventive dentistry and shows good result on the teeth sensitivity (Lyons, 2014). Nano-HAp is used to improve/accelerate the existing/present dental materials as an additive material in the regeneration field. It has been mostly used in maxillofacial and oral surgery because of its some unique properties (such as; non-toxicity, bone reconstruction, strong chemical bond to bone) (Melchels *et al.*, 2012). Nano-HAp is also used as fillers because it repair small cracks and holes present on teeth surface. Calcium HAp is a manufactured material indistinguishable to the substance in teeth and bones (Tumbleston *et al.*, 2015; Venkatesan *et al.*, 2015). It is HAp that gives accelerated growth for damaged bones (Wei and Ma, 2004; Wohlers, 2014). Nano-HAp is a characteristic mineral type of calcium apatite that synthetically looks like the perplexing framework of bone. The nano-HAp is a constituent of bone (around 70%) and is utilized to expand the auxiliary unbending nature of platforms, guaranteeing their appropriateness for bone tissue development methodology (Wu *et al.*, 2014).

The nano-HAp is exceedingly osteo-conductive and displays bone bonding limit, offers a suitable layout structure for bone arrangement, and advances cell working permitting the outflow of bone framing osteo-genic markers (LeGeros, 2002; Venkatesan *et al.*, 2015). The nano-HAp is frequently functionalized with different polymers, for example, PLA, polyetheretherketone (PEEK) and chitosan (CS), to give the mechanical properties required to an embed in the reconstruction and regeneration of bone, tissue (Wei and Ma, 2004; Mangano *et al.*, 2006; Piccirillo *et al.*, 2013).

HAp has attracted more attention in biomedical fields due to its exceptional features such as biocompatibility, bioactivity, osteo-conductivity and osteo-inductivity. HAp has similar structural and chemical resemblance to teeth and bone due to its key inorganic phosphate (Orlovskii *et al.*, 2002; Huang *et al.*, 2011). Bioactivity and biodegradability of HAp generally depend on the Ca/P ratio, crystallinity and phase purity. The appropriate Ca/P ratio for preparation of HAp is 1.67. There are different methods for preparation of nano-HAp including wet chemical, hydrothermal, solid-state reaction, sol-gel and microwave processes. Wet chemical approach possesses several advantages over the other preparation techniques that include low processing temperature, cost-effectiveness, simplicity and production of the highly pure products. Furthermore, this method is able to generate nano-crystalline powders, bulk amorphous nano-particles and thin films. Table 1 shows the chemical composition, and physical properties of PLA and nano HAp used in present study.

The literature review reveals that some studies have been reported on use of PLA, HAp in biomedical applications, but hitherto very less has been reported on use of cryogenic environment while crushing of matrix and reinforcement material (to get uniform dispersion of nano HAp particles in PLA matrix) for preparing partial dentures. In this study detailed procedure for preparation of nano HAp reinforced PLA matrix based partial denture has been outlined by using 3D printing. For experimental analysis, four different proportions of PLA and nano HAp blend have been selected for preparation of biocompatible feedstock filament by using commercial TSE. After selection of best-feedstock filament, based upon MFI, thermal analysis and tensile strength, FDM based 3D printer has been used for printing of partial dentures.

Materials and Methods

Fig. 1 shows process chart for development of partial denture from nano-HAp composite polymer prepared with cryogenic grinding mill.

Table 1 Chemical composition and physical properties of PLA and nano HAp

PLA (Matrix material)		Nano-HAp (Reinforcement)	
Chemical formula	(C ₃ H ₄ O ₂) _n	Chemical formula	Ca ₅ (PO ₄) ₃ (OH)
Density	1.210–1.430 g/cm ³	Density	2–6 g/cm ³
Young's modulus	3.5GPa	Young's Modulus	60–100 GPa
Glass transition temperature	60°C	Glass transition temperature	– 30°C
Melting temperature	162–178°C	Melting temperature	1100°C
Thermal conductivity	0.13 W/mK	Thermal conductivity	10–15 W/mK
Specific heat capacity	1800 J/kgK	Specific heat capacity	653 J/kgK
Applications	Extrusion, injection moulding, spinning for wide range of materials	Applications	Bone grafting, dental prosthetic and repair

Note: PLA procured from Natur-Tec India Pvt. Ltd. (Tamilnadu, India), HAp procured from Intelligent materials Pvt. Ltd. (Dera Bassi, India).

**Fig. 1** Flow chart for printing of partial dentures.

Polymers are commercially available in granules form. For reinforcement of biomedical polymers (granules) with biomedical ceramics (nano-HAp) both should be in powder form for proper mixing. Biocompatible polymers need to be grounded without losing their biomedical properties. For this reason the polymers blended with required reinforcements are grounded at cryogenic temperature (– 50°C to – 196°C). Liquid nitrogen is most commonly used liquid gas in cryogenic grinder due to easy availability. For development of partial denture by 3D printer (open source FDM) initially biocompatible feedstock filaments needs to be prepared with the help of extrusion process. Further in this study for high strength and precise diameter of the feedstock filaments, TSE has been used.

In this article, nano-HAp has been reinforced with biocompatible and biodegradable PLA. For better reinforcement, PLA granules were cryogenically grounded by using commercial setup (Make: RETSCH Cryo-mill, Germany). Initially the PLA granules were processed with Ø25 mm stainless steel ball in 50 ml capacity stainless steel grinding jar for 10 min (5 min precooling and 5 min during grinding) at – 196°C. After that in second stage for less average diameter of PLA granules Ø12 mm stainless steel ball (4 stainless steel ball) in 50 ml capacity stainless steel grinding jar for 10 min (5 min precooling and 5 min during grinding) at – 196°C were used. After grinding of PLA (which was commercially available in granule form), final blend with nano-HAp of different proportion was prepared. Following 04 different proportions/compositions were further investigated: (i) 100% PLA, (ii) 96% PLA-4% HAp, (iii) 94% PLA-6% HAp, (iv) 92% PLA-8% HAp. The blend is further used to fabricate the feedstock filament using TSE at optimized settings. After that for selection of best feedstock filament rheological, tensile and thermal analysis are performed on MFI tester, UTT and DSC respectively. Finally, partial denture of feedstock filament of PLA granules (cryogenically treated) and reinforced with nano-HAp are ready to be used in open source FDM.

Cryogenic Grinding of Biocompatible Polymer (PLA)

Biocompatible grades of PLA are commercially available in granules/rod/sheet/feed stock filament form. **Fig. 2** shows 3D view of Cryo-Mill setup which was attached with liquid nitrogen cylinder. **Fig. 3** shows that 3D view of stainless steel cryogenic grinding jar with capacity of 50 ml. In cryogenic grinding following steps are being followed:

- (1) Charging of vibrating jar (usually up to 1/3rd capacity by volume) and grinding balls as per requirement (see **Table 2**),
- (2) Pre-cooling with flow of liquid nitrogen in vibrating chamber (at frequency of 5 Hz),
- (3) Cryogenic grinding (at frequency of 25–30 Hz) at – 196°C.

Fig. 2 3D view of Cryo-Mill setup.

Fig. 4 show the different size of grinding balls of stainless steel (Ø25, Ø20, Ø15 and Ø12) and zirconium (Ø 10). In this study Ø15 stainless steel grinding balls has been used.

Results and Discussion

Fabrication of Nano HAp-PLA Composite Feedstock Filament

For short listing of best proportion of PLA-nano HAp, initially four proportions were selected and subjected to MFI analysis as per the ASTM standard (D 1238-95) (see **Table 3**). All four proportion of PLA-nano HAp reinforced composite were fabricated on TSE, make: HAAKE Mini CTW, Germany. The fixed parametric settings of TSE were: barrel temperature 190°C, 140–150 rpm with 10 kg applied load. After this the composite material was put into the pre-heated barrel of MFI tester. The MFI values for all 04 proportions are also given in **Table 3**.

3	94%–6%	54.97	151.39	53.74	149.62	53.99	149.62
4	92%–8%	56.61	151.72	53.06	148.44	52.81	147.13

**Fig. 6** 3D printed polymeric partial denture.**Fig. 7** Surface roughness profiles of replicas (a) before smoothing (b) after smoothing for 20 s.

Tensile Testing

In this part of experimentation, all four compositions of feedstock filaments were checked from strength point of view (see Table 4).

Based on Table 4, it has been ascertained that all four compositions are having good strength but PLA 96% – nano HAp 4% (see S.no. 2, Table 4) have been selected for further experimentation because it resulted into better mechanical properties than other compositions (see S.no. 3 and 4, Table 4). The mechanical properties for PLA 96% – nano HAp 4% are comparable to virgin PLA. Further as reported in literature nano-HAp reinforcement will result into better biocompatibility as compared to virgin PLA.

Thermal Analysis

In this experimentation part, all four compositions feedstock filament of PLA polymers reinforced with nano HAp ceramics were subjected to thermal analysis. Thermal analysis for all four compositions was carried out by METTLER TOLEDO, Model DSC3; Swiss make with STAR[®] (SW 14.00) software under N₂ gas environment. Fig. 5 and Table 5 show the thermal analysis curve and value of four different biocompatible feedstock filaments.

As observed from Table 5 and Fig. 5 no significant difference in glass transition temperature and melting temperature of all four feedstock filaments was observed. Finally, from all experiments (results of MFI, tensile testing and thermal analysis on DSC) it was

ascertained that for fabrication of feedstock filaments, best materials (PLA polymer granules reinforced with nano HAp) proportions/compositions was selected as 96% PLA – 4% nano HAp (by weight percentage).

The prepared feedstock filaments were used on open source FDM for fabrication of partial denture. For fabrication of partial denture at first stage partial denture CAD file was generated and stored in STL format. Fig. 6 shows that sample of 3D printed partial denture.

The 3D printed partial dentures were observed with micro surface defects (like staircase effect). For minimizing these defects, acetone vapor bath smoothing process was applied on fabricated partial dentures. Acetone was chosen for the smoothing process due to its low cost, low toxicity, and very high diffusion. The interaction of acetone and PLA does not result in a chemical change in the PLA material. Fig. 7 shows surface roughness profile before and after chemical vapor smoothing. The samples exposed for three cycles for 20 s each showed 80%–87% reduction in average surface roughness (Ra).

Conclusions

The present study provides a comprehensive frame work for preparation of partial dentures with biocompatible polymer matrix composite. In this study biocompatible PLA was blended with nano sized HAp particles at cryogenic environment. Based upon mechanical (tensile) and rheological (MFI) properties 96% PLA – 4% HAp was selected for fabrication of feedstock filament for FDM. Finally the surface finish of 3D printed partial denture was improved (from 80% to 87%) with chemical vapor smoothing process.

Introduction

Surfaces and near-surface regions of engineering components fulfill multiple functions and play important roles in controlling the service life of materials against environmental deterioration caused by wear and corrosion effects (Petrova and Suwattananoni, 2005). Wear is a surface-dependent property and wear resistance characteristics can be improved by appropriately tailoring surface microstructure and/or composition, without affecting the soft, tougher core parts of the bulk material. Until recently, surface modification of ferrous and nonferrous alloy substrates has been achieved using a localized heat treatment methods based on diffusion-controlled hardening processes including carburizing, nitriding, carbonitriding, or chromising. The heat treatment processes have been employed to induce phase transformation (bainite or martensite) in steels, which improve hardness and wear resistant performance characteristics but this occur by sacrificing other properties such as toughness and ductility. In addition, the achievable hard surface layer of 2–3 μm deposited by physical or chemical deposition from a vapor phase techniques (CVD or PVD) are unacceptably thin for modern engineering applications involving abrasive wear and high temperature. These coatings fail by delamination along the coating interface during impact loading (Maleque *et al.*, 2013; Khan, 2007). In this situation, formation of a hard composite layer by the use of surface melting and addition of ceramic particles onto the near-surface region of steel materials have the potential to modify surfaces while retaining the bulk properties of the steel. This process of surface engineering offers a wide range of possibilities to achieve desirable surface characteristics to meet up with the challenges of emerging technologies and applications (Mridha *et al.*, 1988).

Over the years, weld overlay techniques based on laser and electron beam are the possible power sources, which provide a high energy density required for addition of ceramic particles onto melted surfaces. The processes have been successfully used with some ferrous alloys but the components of these energy beams are very complex, expensive and as well require high precision system control and monitoring. Recent attempt has shown that tungsten inert gas (TIG) arc heat source has potential for producing surface composite coating with sufficient engineering thickness. In this treatment, ceramic powder of desirable composition and a thin surface layer of the substrate material are simultaneously melted under TIG torch arc and then allowed to rapidly solidify to generate dense composite coatings, which are metallurgically bonded to the substrate material. In contrast to other techniques, TIG surface welding process is simpler, cost effective, and flexible alternative (Munoz-Escalona *et al.*, 2016; Bello *et al.*, 2016; Ding *et al.*, 2007; Hojjatzadeh *et al.*, 2012).

The aim of the present review is to describe the overview and philosophy of ceramic-based composite coatings and coating technologies. The emergence of tungsten inert gas (TIG) arc welding process as a necessary alternative heat sources for depositing functional composite coatings has also been reviewed in this paper. Brief description of the art of TIG torch arc melting process are given, including the TIG torch coating scheme, fluid phenomenon and process parameter control. The microstructures of TIG modified composite coating system as well as their tribological performances are equally discussed.

Overview of Ceramic Composite Coating Technologies

Ceramic composite coatings generally include hard particles distributed in the near surface layer of metallic matrices. They have advantages in the perspective of properties such as high wear, corrosion resistance and ability to work at high temperature. Due to these potential benefits, varieties of composite coatings are being studied upon and are being developed for use in maintaining wear and controlling friction. Hard coatings have been successfully used particularly to enhance the life of some important alloy substrates (low alloy steel, stainless steel, titanium, magnesium, etc) for various industrial applications as found in automotive, aerospace, machinery and chemical industries (Wang and Zhang, 2014).

The practice of surface coating has a long history of generating metal matrix composite (MMC) coatings or films for providing high surface hardness combined with adequate resistance against wear, corrosion and high temperature effects. The history of hard coating development can be traced back to 1838 when Michael Faraday developed a deposition technique with the existence of vacuum established by Evangelista Torricelli in 1643. This famous technique started to gain attention until when cutting tools coated with TiN was produced in the 1960 in U.S. industry. Unlike developments in bulk materials, many of the advances in surface coating have been motivated by tribological needs of the modern technologies, and this will continue to play a major role in the future. Surface coating route do not only afford surfaces with good tribological properties, but also largely contribute to the conservation of scarce and expensive high-performance materials by concentrating the hardfacing treatment into a surface layer of the substrate (Stachowiak and Barchelor, 2005; Holmberg and Matthews, 1994).

The philosophy in the fabrication of ceramic-based surface composite coatings was due to the natural ability of ceramic phase materials to exhibit rather low friction and low wear under specific conditions such as high loading, speed and temperature. Hard

wear-resistant composite coatings are mostly generated from hard particles of metal carbides such as TiC, SiC, Cr₃C₂, SiC, B₄C, WC and VC (Erdemir, 2001; Holmberg and Matthews, 1994).

Over the years, variants of advanced hard surface coatings methods have been used for depositing a modified layer of both thin and thick coatings in the range of 0.001–20 mm on LAS substrate, depending on the application requirement. These coating techniques include vacuum deposition (e.g., physical vapor deposition (PVD), chemical vapor deposition, CVD), electro-deposition (e.g., electroless, electroplating etc), melting, and alloying deposition processes (e.g., hardfacing by welding, laser cladding, and thermal spraying). Of these techniques, only the surface modification of materials by process of melting and alloying, which uses concentrated heating sources, is suitable for depositing relatively thick functional hard coatings for tribological use. This serves as an advantage over CVD or PVD techniques that can only deposit thin hard coatings of 1–10 µm layer, which seems unsuitable for many applications involving impact-loading condition (Wang and Zhang, 2014; Shipway, 2006).

Ceramic Particles for Composite Coating Reinforcement

A variety of engineering materials can be modified by other expensive bulk processing using alloying, mixing, compositing, and organic coating to achieve adequate resistance to wear, corrosion and friction. Diffusion methods such as nitriding, carburizing, carbonitriding, nitrocarburizing, boriding and aluminizing are also used to harden materials but this process is time consuming and provides limited maximum hardness. However, structural ceramic particles appear to be ideal wear-resistant materials to offer a comprehensive protection against surface wear issues (Bachelor *et al.*, 2002).

Depending on the wear environment and other specific application, wide varieties of ceramic particles are available and can be selected as coating materials on steel substrates to mitigate tribological and corrosion behavior. The common inorganic ceramic compounds used as reinforcing particles in steel matrices include borides (TiB), carbides (TiC, WC, SiC, B₄C, VC), nitrides (TiN, BN), and oxides such as Al₂O₃ and ZrO₂ (Subramanian and Strafford, 1993; Du *et al.*, 2011). These reinforcements are formed mostly from transitional metals and elements of Groups IV and VI in the Periodic Table. Du *et al.* (2011) reported these coating materials have significantly contributed to the development of a series of wear-resistant coating systems. In selecting a coating material, the important material parameters to be considered in achieving better performance are the properties of the coating material, resistance of the coating material to the attack expected, chemical compatibility of the coating and substrate materials and the cost (Subramanian and Strafford, 1993).

Tungsten Inert Arc Torch Welding Technology

Like other surface coating techniques, the use of surface melting and alloying treatment has potential to tailor the intrinsic properties of steel surfaces, while retaining the bulk mechanical properties of the substrate. The application of this thermal hardening method is only possible using the concentrated heating source including high power laser beam, electron beam, thermal flame spray and electric metal arc radiations. Until recently, high energy density beam from laser is widely used to produce thick, high-density ceramic coatings on a range of engineering components to enhance surface properties with superior resistance to tribological phenomena like wear, friction or oxidation resistance (Khan, 2007). The process of laser surface treatment has, therefore, become an important method to produce ceramic hard coating on metallic materials for various tribological uses. However, the applications of laser beam coating techniques for processing such composite layers are limited by many factors such as costly manufacturing procedure, expensive initial investments and precision control of the system (Bello *et al.*, 2016; Hajbagheri *et al.*, 2008). Hence, an alternative heat sources must be considered to generate high energy density that would give more suitable and cost-effective composite coatings.

Recently, another surface coating technology route has emerged based on an electric arc produced by Tungsten Inert Gas (TIG) torch welding. TIG torch welding process originated in the USA in 1930s and was used mainly to facilitate the then rather difficult process of welding aluminum. The process was also known as gas tungsten arc welding (GTAW) and the tungsten arc heat source has shown potential to be used to melt surfaces in a controlled manner for generating composite coating on LAS materials. As shown in Fig. 1, TIG surface coating process utilizes electric arc energy density created between a non-consumable tungsten electrode and the substrate for processing composite layers, which are reported to increase hardness and wear resistance markedly. The adoption of this novel fabrication process is geared towards developing a more simplified and cost effective process of applying hard surface coatings on engineering components such as steels and some nonferrous (Idriss and Mridha, 2012; Hajbagheri *et al.*, 2008).

Fig. 2 further illustrates a typical surface coating scheme based on TIG surface alloying process. In this method, an electric torch with adequate energy density is scanned over a substrate material predeposited with alloy powder of a desirable composition (Fig. 2, section a). A thin surface layer of the substrate absorbs heat energy from traveling TIG torch arc (section b) and become melted at high treatment temperature of the system. As shown in Fig. 2 (sections c and d), rapid mixing of the liquid melt with the preplaced powder occur leading to the formation of the surface melt pool layer from the remelted materials, which sinks towards the substrate by a convective flow to a depth depending on the TIG heat input. Thus, the formation of melt pool begins at the substrate surface through which ceramic particles are introduced to produce composite layer. The occurrence of the intensive mixing in the remelted zone has been attributed to the shear stresses developed in this

Fig. 1 Schematic diagram of TIG melting process. Available at: <https://nptel.ac.in/courses>.

Fig. 2 Schematic diagram showing the various stages involved during the TIG surface melting and cladding process.

region due to the effect of a large thermal distribution gradient between the hot molten metal and the cooler ceramic particles. This process is important as it affects the form of convection flow and the ultimate distribution of the alloying element along the melt pool of the TIG torch modified surfaces (Kuo, 2003). Afterwards, rapid solidification of the remelted layer begins due to the heat dissipation to the cold substrate via the heat affected zone and it thus completes with the formation of dense coating metallurgically bonded to the substrate material (Fig. 2, sections e and f). This rapidly solidified structure obtained by this treatment may contain modified alloy layer of $X_a Y_{1-a}$ (Fig. 2, section f) composition in the steel matrix, which may give rise to new components with high hardness and high resistance against wear, corrosion and temperature. For different applications, TIG welding technique can provide a wide range of possible coating system with single or multi-component, and also of the composite or gradient types. Other advantages offer by TIG coating process lies with its flexibility in operation, economical in time, energy, and material consumption, and low initial capital investments when compared to other conventional processes (Celik *et al.*, 2011).

Fluids Flow Phenomenon in TIG Arc Melting Process

TIG torch welding and alloying process is a relatively new liquid-phase surface treatment technique for metals and alloys in many tribological applications. In this process, the coating efficiency is completely controlled by the microstructure of melt pool and heat affected zone (HAZ). It is well known that the mode of fluid flow field experienced by the melt pool and HAZ during TIG arc melting can alter the microstructure and thus the properties of the coating layer. Therefore, this phenomena fluid flow in the melt pool can significantly influence such factors as the melt pool geometry, the temperature gradients, the heat transfer rates and the resolidified structure. The development of fluid-flow fields in liquid pool is induced by the transporting phenomena from the TIG

electrode arc to the metallic substrate, such as arc current density, heat flux, arc pressure and induced shear stress acting on the weld pool surface (Kuo, 2003; Oreper and Szekely, 1984).

Process Parameters for TIG Welding

Unlike conventional high-energy beam heat sources (such as laser, electron beams and other arc sources), the TIG fusion welding process is a low energy technique that guarantees quality weld surface with minimum defect and production cost. The low-energy TIG melting process is endowed with other attractive features such as flexible power requirement, limited heat inputs, highly autogenous and quite suitable for steel alloys and most reactive metals, such as titanium, zirconium, aluminum and magnesium. Due to these inherent benefits, TIG arc surface melting and alloying is gaining popularity among the current trend in hardfacing (liquid phase surface) treatment of steels via incorporation of ceramic composite powder of desirable composition (Kuo, 2003; Hojjatzadeh *et al.*, 2012).

Many investigations have been conducted using TIG torch as heat sources to achieve composite melted surface layer, which are reported to tailor the structure and properties of steel surfaces against wear and friction. TIG modified surfaces are strongly characterized by the quality of the melt pool. This is because melt pool conditions play a significant role in determining the microstructure and properties of the coated layer. Numerous investigators also observed that the resolidified structures and properties obtained in TIG melted surfaces can be controlled over a wide range by selecting and adjusting desired welding process parameters during the melting process. Among others, TIG welding process is usually controlled by some variables such as arc current, traversing speed, shielding gas flow rate and arc voltage. It is also considered that TIG can be used to deposit coating layer with varying addition of ceramic powder composition and content (Eroglu and Zdemir, 2002; Kuo, 2003; Mridha *et al.*, 2012).

Peng (2012) studied the effect of process variables including current, speed, arc gap and argon gas flow rate on the surface features of surface alloyed carbon steel with TiC particles by using TIG process. The author demonstrated that surface hardness was affected more obviously by the welding speed and welding current than other experimental factors. At a lower speed, the surface hardness was found to decrease with increasing current. Under this condition, both concentration of ferrite and melt dilution content was claimed to increase, which might have contributed to the less dispersion of TiC particles in the melt pool and reason for low hardness development for the treated sample surfaces. It is therefore, noted that the higher the ferrite content due to the dilution from the substrate, the lower the cladding hardness. The surface hardness of the TIG-melted steel seems, however, not to correlate with the arc gap size and the shielding gas flow rate. The author further established that wear resistance and coefficient of friction also depend mainly on the combination of welding current and speed processing conditions, but are independent of electrode arc gap and argon gas flow rate. The wear resistance was measured based on area and depth of wear scar. The study showed that wear scar geometries in the coated samples rapidly increased with increasing current from 120 (A) to 180 (A). This suggests that the lower the scar area, the higher wear resistance. At the lower welding current, wear surfaces of the TiC coating had clean and smooth morphologies in contrast to the severe adhesive wear scar experienced by the untreated carbon steel. The adhesive feature was characterized with microcutting and grooving. Similarly, a lower friction coefficient in this study was obtained under the same optimum condition. A combination of lower welding current and lower welding speed were found, in this study, to be important requirement for the excellent surface wear features observed in TIG alloyed surfaces. This was attributed to the higher hardness of the composite coated surface reducing the asperity contact of the mating materials.

Kuo (2003) reported the influence of welding speed and welding current on the solidification mode of TIG-melted pool in HY-80 steel. Under the same welding speed, the result showed that the melt pool microstructure changes from cellular to dendritic resolidified structures as the welding current increases. The author also observed that the cooling rate increases with increasing speed, under the same applied arc current. It is therefore concluded that the higher welding speed resulted to higher cooling rate and the cells are finer, while the lower speed produced lower cooling rate and coarser resolidified structures.

The effect of shielding gas parameters (types, flow rates and compositions) on the performance of TIG coated and modified surfaces have been studied extensively by many authors (Hojjatzadeh *et al.*, 2012; Wang *et al.*, 2007). The authors proposed that the current density distribution in TIG arc process largely depends on the type of shielding gas. In addition, the authors revealed that among the three shielding environment investigated, argon gas produced the best arc characteristics based on the account of its low ionization potential. The studies demonstrated the effectiveness of using argon gas as the main shielding gas during TIG surface treatment experiments. Shielding gas flow rate is another parameter that also influences the behavior of melt pool structure during TIG arc welding process. The authors also reported an increase in the melt pool bead width and depth as the gas flow rate increases.

Efforts were also made to examine the effects of welding voltage parameter on the surface modification routes with TIG arc heat sources. Mridha *et al.* (2012) investigated the effect of arc voltage on the property behavior of TIG-processed steel alloys. The study revealed that variation in the applied voltage between 30 V and 55 V yielded composite tracks with different microstructural and hardness evolution. Based on the review of the previous studies on TIG surface treatment scheme, it is identified that the structure and performance of TIG-modified surfaces are influenced by multiplicity of key independent parameters ranging from arc welding current, electrode travel speed, welding voltage, polarity, current supply technique (pulsed or continuous), pre-coated powder content, arc length, shielding gas composition and flow rate. The flexibility in controlling these parameters during TIG arc melting process and their corresponding influence on mechanical and tribological performance of engineering remains a new direction for future research in ceramic reinforced composite coatings (Bello *et al.*, 2015; Juang and Tarnag, 2002; Maleque *et al.*, 2013).

Fig. 3 Schematic flow of powder preplacement process for TIG-based composite coating.

Processing of TIG-Based Ceramic Reinforced Composite Coatings

The feasibility attempt of processing a hard ceramic composite coating by melting engineering alloy surfaces beneath TIG torch arc was initiated by the work of [Mridha et al. \(1988\)](#) and since then many studies have been reported by several researchers on this novel coating technology. TIG surface modification has been used for repairing the worn surface of machine parts and hardfacing of ferrous materials in various industrial applications such as mining, chemical, and petroleum industries. TIG cladding process is usually performed on ferrous alloy (cast-iron, non-alloy carbon steels and alloy steels) and non-ferrous alloy (commercial purity titanium) substrate materials. In TIG-based composite coating, an alloy or a composite layer is usually fused onto the surface of the substrate based on the two-step fabrication process using ceramic powder preplacement and TIG torch melting technique.

Preparation of Ceramic-Powder Preplaced Surfaces

The first step of TIG-based composite coating method is to prepare and place ceramic powder material on the surface of a chosen substrate using powder preplacement process. At first, the surface of the substrate samples is ground and polished to a desired surface roughness using SiC abrasive paper. The polished substrate is then thoroughly degreased in acetone in order to remove any impurities such as grease, dust, and oxide layer from the substrate surface. The ceramic powder is selected based on the requirement of the intended surfaces. The two or more powder material are usually mixed and blended together using a low energy ball-milling machine between 10 and 60 min and ball-to-powder weight ratio (BWR) of 5:1 or 10:1. The powder mixture is weighed at approximate content of 1.0 mg per millimeter square area of the substrate surface. This is mixed with a predetermined amount of organic binder (4% polyvinyl alcohol, PVA), distilled water and alcohol to form a past-like solution or a slurry. Organic binder is used to prevent the powders from blowing away under the flow of shielding gas during TIG glazing operation. The amount of binder used is usually restricted to within the limit of 0.5 ml for 2 mg of powder mixture to prevent excessive pore formation in the resolidified coating layer ([Mridha et al., 1988](#)). The mixed powder paste is dispersed uniformly on the substrate surface with the aid of plastic spatula to form a preplaced layer with desired thickness in the range of 0.5–1.5 mm. The thickness of the preplaced layer is maintained by using the appropriate amount of powder mixture required to cover the surface of the substrate. The approximate thickness of the preplaced layer produced on the substrate surface is measured from the difference in thickness of the substrate before and after the preplacing of powder layer using a Vernier caliper. The preplaced powder surface is then allowed to dry in an oven for 1–5 h at 80–100°C to remove excessive moisture and for ensuring the preplaced powder layer is well adhered to the substrate surface ([Maleque et al., 2018](#); [Munoz-Escalona et al., 2016](#); [Bello et al., 2016](#); [Hojjatzadeh et al., 2012](#); [Wang et al., 2007](#)). A schematic flow of this process is given in [Fig. 3](#).

Surface Melting by TIG Welding

Surface melting of the preplaced substrates is accomplished under the arc torch of TIG welding machine. In this process, the arc generated by the TIG torch welding process, under different conditions, is adapted for the realization of composite coatings by depositing ceramic particles in the melt pool of the substrate. The tungsten inert gas arc process utilizes a localized heat source of an arc created between the tip of a non-consumable tungsten electrode (with varying diameter from 2.4 to 4.8 mm) and the specimen surface as shown in [Fig. 4](#). The arc develops intense heat, approximately 11,000°F (6100°C) which melts a thin surface layer of the base metal to form a molten pool. As depicted in [Fig. 4](#), the TIG heat source or arc is scanned over the preplaced substrate that resulted in melting of the preplaced powder mixture and a thin layer of the substrate underneath the coating layer. The arc is usually controlled by the supply of current (50–110 A) and voltage (10–40 V) to the electrode. The electrode height used is usually maintained between 2 and 3 mm.

During irradiation process, the arc area (weld pool and electrode) is protected from undesirable oxidation by the inert shielding gas such as argon in the range of 10–30 l/min and is channeled through electrode gun. The shielding gas displaces the air, so that the oxygen and nitrogen of the air do not come in contact with the molten metal or the hot tungsten electrode. The preplaced substrate is held stationary under the moving TIG torch at varying electrode-traversing speeds (0.5–3.0 mm/s)

Fig. 4 Schematic representation of surface melting by TIG welding (a) composite coating process and (b) coating specimen. Reproduced from Buytoz, S., Yildirim, M.M., 2010. Microstructure and abrasive wear properties of $M(Cr, Fe)_7C_3$ carbides reinforced high-chromium carbon coating produced by gas tungsten arc welding (GTAW) process. Archives of Foundry Engineering 10, 279–286.

to produce coated tracks along the width of the specimens (Bello *et al.*, 2018; Mridha *et al.*, 2012; Buytoz and Yildirim, 2010; Cheung and Khan, 2003; Eroglu and Zdemir, 2002). The heat input required for the process is calculated using Easterling Eq. (1) (Easterling, 1992):

$$\text{Heat input (J/mm)} = \frac{0.48 \times \text{voltage (V)} \times \text{Current (I)}}{\text{Travel speed mm/min}} \quad (1)$$

Based on the processing conditions, various degrees of heat inputs are generated giving rise to localized heating, melting or evaporation. The application of extremely high power density can increase the melt pool temperature as high as 2000°C to produce high thermal gradients. The microstructure, as well as the composition of the composite coatings depends on the degree of mixing between the molten pool and the ceramic particles. Further, the microstructure of the coating is governed by convection, diffusion, and cooling rates during liquid-to-solid and solid-to-liquid phase transformation. The higher cooling rate produces hard phases and refines the microstructure resulting in solid solution strengthening. Hence, the parameters controlling these mechanisms are of paramount importance to the TIG-based composite coating technology. For the purpose of characterization, both single and multiple coated tracks are produced (Fig. 5). Single tracks are made for the determination of the microstructure and microhardness of TIG modified surfaces. In multiple tracks, series of overlap tracks are clad side by side with an overlap ratio of 25%–50% on the entire surface of the substrate specimen for the tribological test involving friction and wear characterization (Munoz-Escalona *et al.*, 2016; Bello *et al.*, 2016; Hojjatzadeh *et al.*, 2012; Wang *et al.*, 2007; Mridha, 2005).

Fig. 6 Schematic diagram of a typical pin-on-disc wear testing machine.

Characterization of TIG-Based Composite Coated Layer

After cladding process, the surface modified specimens are cut at the transverse direction of arc scanning by using wire-EDM or hack saw for microstructural examination and hardness measurement. The cross sectioned specimen are prepared for metallographic examination by grinding on SiC wheels followed by polishing and etched with an appropriate etchant depending on the base material. For example, titanium based substrates are etched with Kroll's reagent (50% HF, 30% H₂O₂ and 20% distilled water by volume) or with a mixture of 20 vol% HF and 80 vol% HNO₃. Most of the steel based specimens are either etched with ferric chloride solution (25 g of FeCl₃, 15 ml of HCl and 100 ml of distilled water) or with a solution of alcohol and 2% nitric acid. The microstructures of the specimens are then observed by scanning electron microscope (SEM), energy dispersive spectra (EDX), X-ray diffraction (XRD) and their spectra analyses are beneficial for microstructure and elemental analysis of the modified surface. Microstructure examinations of the worn surfaces are also evaluated to determine the phases and wear characteristics of the modified surfaces after wear testing. Hardness measurement is performed on the transverse sections of the produced coating surface using a microhardness tester with a Vickers indenter. A varying load (50–500-gf) at a specified dwell time (5–10-s) is used to create indentations along the melt depth of the composite coated specimen, starting from the surface of the melt zone to the base material (Maleque *et al.*, 2018; Buytoz and Yildirim, 2010; Cheung and Khan, 2003; Juang and Tarng, 2002).

Wear tests are performed on TIG modified specimens to determine their tribological properties (wear and friction). Wear experiments are done either at the room or high temperature with pin-on-disc or ball-on-disc type tribometer. This method consists of a static partner, which is held in contact with a rotating disc via a steel pin. The disc and the pin are arranged in such a way that the static partner served as the counterface material while the rotating disc served as the test samples. Fig. 6 shows the schematic illustration of the wear testing apparatus while Fig. 7 shows a typical high-temperature tribometer. The test specimens for the wear experiment are machined from the TIG-based composite coated surface to the standard dimension and are used as the rotating disks for the wear test. Prior to the test, the contacting surfaces of the test samples are ground with SiC paper abrasives followed by cleaning in acetone and drying in hot air to remove any dirt in form grease and debris (Bello *et al.*, 2018; Adeleke and Maleque, 2015; Peng, 2012; Hajbagheri *et al.*, 2008; Mridha, 2005).

Fig. 7 A typical ball-on-disc apparatus for high-temperature wear testing; (a) TR-20-PHM-CHM-600 DUCOM tribometer and (b) Schematic diagram. Reproduced from (a) Bello, K.A., Maleque, M.A., Adebisi, A.A., Dube, A., 2016. Preparation and characterisation of TIG-alloyed hybrid composite coatings for high-temperature tribological applications. Transactions of the IMF 94 (4), 211–221. (b) Segu, D.Z., Choi, J.H., Kim, S.S., 2012. Sliding wear behavior of Fe-based bulk metallic glass at high temperature. Journal of Mechanical Science and Technology 26 (11), 3565–3570.

The average wear track width is measured with the help of scanning electron microscope and volume loss is obtained using Eq. (2):

$$V = 2\pi R \left\{ r^2 \sin^{-1}(d/2r) - (d/4)\sqrt{4r^2 - d^2} \right\} \quad (2)$$

where R is the wear track radius (mm), d the wear track width (mm) and r is the radius of the pin or ball (mm). Thus, the wear rate (w) is calculated according to the Eq. (3) and expressed as mm^3/Nm :

$$\text{Wear rate} = \frac{\text{wear volume loss}}{\text{sliding distance} \times \text{applied load}} \quad (3)$$

Microstructure and Properties of TIG Processed Composite Coatings

Hardfacing by means of TIG welding method associated with a rapid heating and cooling rate provided a unique opportunity for the non-equilibrium synthesis of materials and produced rapidly solidified fine microstructures with extended solid solution of alloying elements, thus providing remarkable enhancement on corrosion resistance, wear resistance without impairing the bulk properties. Studies conducted on ceramic reinforced composite coatings produced by TIG torch welding method have identified that both the hardness and tribological resistance development are directly related to the melt pool microstructure of the composite coatings (Munoz-Escalona *et al.*, 2016; Hojjatzadeh *et al.*, 2012; Mridha, 2005).

Microstructural Features of the Composite Coatings

Processing of composite coating by TIG torch arc melting results in microstructural evolution with non-equilibrium structures, which are formed under high cooling rates. Hence, the melt structure developed in the ceramic-based coating is related to the extent of melting, solidification process. The cross sections of the re-solidified surface layers are examined by optical and scanning electron microscopy while the elemental, and phase constituents of the coating are determined by energy dispersive spectrograph (EDS) and X-ray diffraction (XRD) analysis. Xinhong *et al.* (2006) realized the application of TIG cladding of AISI 1040 steel with TiC particles reinforced composite coating. Pre-coated FeCrBSi alloy, graphite and ferro-titanium powders on the substrate produced the in situ coating. The authors in their work revealed when the pre-coated thickness of the mixture powder is less than 1.2 mm, the melt tracks were found to be free from gas porosity, inclusions and crack (Fig. 8(a)). Melted tracks gave a smooth rippled surface topography. However, when the thickness of the pre-coated thickness is beyond 2.0 mm, the formation of the tracks became poor, gas porosity and incomplete fusion can be found, as shown in Fig. 8(b).

Bello *et al.* (2018) produced two Fe-based ternary composite coatings by depositing two different powder preplaced mixture (PPM) with nominal percentage compositions of 94Fe4C2Si (PPM1) and 90Fe6C4Si (PPM2) on CP-Ti using TIG cladding process. As shown in Fig. 9, the analysis of the coatings revealed that the microstructure in the melt consists of dendrites of different sizes. At lower powder preplaced mixtures (PPM1, Fig. 9(a)), the dendrite size was larger compared to higher powder

preplaced mixtures (PPM2, [Fig. 9\(b\)](#)). The enlarged dendrites in the PPM1 composite layer track are thought to be associated with higher dissolution of PPM in Ti melt matrix. Also, the amount of carbon is believed to have influenced the growth of dendrites and their concentration in the melt.

Furthermore, the EDX analysis of the dendritic structures in the clad layer revealed that the peaks are mainly from Ti and C ([Fig. 10\(a\)](#)), indicating the in situ formation of TiC in the composite coatings. The high affinity of carbon to titanium is significant to produce such TiC phase. As revealed in [Fig. 10\(b\)](#), the X-ray pattern from the surface of the specimen processed with PPM1 also revealed that the melt structure contains TiC (dendrites), iron carbide and Ti_3SiC_2 (melt matrix).

Microhardness of the Composite Coatings

[Hojjatzadeh et al. \(2012\)](#) have investigated the surface melting of AISI 1045 steel with a preplaced layer of ferro-titanium powder in the presence of a gaseous shield of pure nitrogen, pure argon and via TIG welding process. The results demonstrated that the addition of the gases significantly increased the surface hardness due to the formation of dendrites of TiN and TiC in the composite layer microstructures. [Peng \(2012\)](#) explored the possibility of the formation of TiC-reinforced composite coatings on AISI 1020 carbon steel surfaces by melting of preplaced titanium carbide powder using tungsten inert gas arc process under varying welding parameters. The author showed that precipitated TiC phases formed in the modified layers had substantially improved to over 65 HRB as compared to that of the steel substrate (6.6 HRB). The TiC-reinforced surface also revealed a higher wear resistance and lower coefficient of frictions compared to the substrate material. [Wang et al. \(2007\)](#) reported microhardness improvements by TIG surface alloying of AISI 1045 steel with preplaced powder mixture of graphite, Fe-Ti and Fe-Cr. The study showed that the hardness

Fig. 10 X-ray analysis of the TIG composite coated specimen (a) EDX of the dendritic structure, and (b) XRD pattern of PPM1 track clad layer.

improvement reduced the wear rate of the TIG alloyed surface to almost four times of that of the untreated material. The authors further demonstrated that the properties of coatings are influenced by the chosen welding variables and thickness of the preplaced powder layer. [Dyuti et al. \(2011\)](#) used TIG heat source to produce intermetallic and nitride claddings on plain carbon steel surfaces with preplaced mixtures of titanium and aluminum powder, under a pure nitrogen-shielding environment. Upon solidification, the authors found that dendritic phases of Ti-Al nitrides and Ti-Al intermetallics were formed in the resolidified layers, which led to an increase in the microhardness of the modified layers by over 4.5 times that of the untreated carbon steels. [Xinhong et al. \(2006\)](#) showed a typical microhardness profile of TIG reinforced composite coated layer of Fe-TiC ([Fig. 11](#)). As shown in the figure, the microhardness of the coating gradually increased with increase of distance from bottom of the coatings. It is noted that there is no sudden transition from the coating to the substrate in the hardness, which indicates an absence of a sharp demarcation in materials properties across the interface.

Tribological Behavior of the Composite Coatings

It is well accepted that the wear and friction characteristics of the composite coating largely govern by the constituent percentage, its microstructure and processing parameters. Hence, it is essential to understand the surface wear characteristics of TIG torch processed coatings. [Elahi et al. \(2012\)](#) compares the variation of the weight losses of the worn surfaces against sliding distance for the as-received and TIG surface coated magnesium alloy. It is observed that the amounts of the weight losses for the untreated substrate and the alloyed layer after 300 m sliding distance are 10.7 mg and 6.1 mg respectively. This indicated that the wear rate of the alloyed sample is almost half of that of the as-received material, which could be attributed to higher hardness of alloyed layer as compared with the hardness of the as-received material. Furthermore, [Buytoz et al. \(2005\)](#) demonstrated that AISI 4340 steel surface treated with WC by using TIG process at high powder feed rate, low process speed and high heat input gave minimum mass loss. [Xinhong et al. \(2006\)](#) in their work revealed that TiC reinforced composite coatings produced by TIG torch melting technique are effective in improving wear resistance and give a much lower increase in wear volume with increasing normal load than that of AISI 1045 steel substrate ([Fig. 12](#)). This is mainly related to the hard carbides of TiC particles. Additionally, amongst the coatings and substrate, the lowest wear volume occurred for the cladding coating with a 1.2 mm thickness of the pre-coated coating and this may be directly attributed to the high hardness achieved with the composite coatings.

[Xinhong et al. \(2006\)](#) further analyzed the SEM micrograph of the worn scar for the TIG modified composite coating with a preplaced TiC layer of 1.2 mm thickness and that of AISI 1045 steel substrate ([Fig. 13](#)). The authors in their work demonstrated that in situ TiC particles reinforced Fe-based composite coating suffered a mild wear with fine scratches, but 1045 steel showed a severe adhesive wear with scale like feature. Due to the hard barriers effect of TiC particles, the scratching was interrupted or the path of scratching was converted. That is in situ synthesis TiC particles reinforced the matrix and protected it from serious abrasion. As a result, the composite coatings possess a much higher resistance to plastic deformation and scratching than that of 1045 steel.

Very recently, [Bello et al. \(2016\)](#) produced TiC/BN and TiC/Ni-P-hBN composite coatings on AISI 4340 steel by TIG cladding process, where BN and Ni-P-hBN act as solid lubricants for high temperature lubrication ([Fig. 14](#)). The wear rates and coefficient were determined for these composite coatings tested at elevated temperature of 600°C ([Fig. 14\(a\)](#)). As shown in the figure, the result of the experiment revealed that the wear resistance of TiC/Ni-P-hBN track layers is over five times higher than that of TiC, or twice that of TiC/hBN coated surfaces.

The authors also demonstrated that the surface coating with TiC reinforcement exhibited coating failure at an early stage of testing (nearly 8 min), which could be related to the poor frictional property of the single-phase coating at elevated temperature. For TiC/hBN hybrid composite coating, the friction coefficient was initially low and quite unstable. It then increased up to 0.62

and remained almost constant throughout the sliding experiment (Fig. 14(b)). The poor frictional control obtained in this class of coating could be attributed to the weak coating strength caused by the presence of non-wettable hBN lubricant powder in the coating architecture. Compared with TiC and TiC/hBN composite coatings, the friction coefficient obtained under the same processing for the TiC/Ni-P-hBN coating exhibited lower and more stable friction throughout the sliding test. It can be seen that

reinforcement of TiC coating with Ni–P–hBN powder is effective in improving frictional behavior and has the lowest coefficient of friction.

Summary and Future Outlook

The present article gives overview of the various surface coatings technologies, which have been evolving over the years. In particular, it outlines newer method of developing ceramic composite coatings on metallic materials via powder preplacement and TIG torch welding process. Although most of the commercially available composite coatings are processed by laser cladding method, the researchers are in constant search for a cost-effective approach, which may offer promising corrosion and wear resistant properties. From this review, TIG arc melting has therefore established its potential to fit in that space and has emerged as a viable replacement to the conventional laser surface treatment due to the complexity and high costs of the laser equipment. This study reveals TIG melting parameter and ceramic composition designs as a key factor in improving composite coating characteristics to give a low wear rate and coefficient of friction values. In future, a thorough study on the new composite coatings added with electroless nickel coatings may offer promising benefits in the development of self-lubricating coatings for tribological applications where components are operating under extreme environment. The authors of this article have developed TiC/Ni-P-hBN hybrid composite coatings with an attractive tribological properties at elevated temperature up to 800°C. With the technological advancement, TIG arc technology could have a bright future for the development of nano-composite coatings and functionally graded coatings using additive manufacturing for advanced tribo-systems in industrial application.

Acknowledgments

The authors would like to thank the Research Management Centre (RMC) of International Islamic University Malaysia for their part in funding this research through project No. RMGS1212-007-0020. One of the authors (K.A. Bello) is equally grateful to Ahmadu Bello University Zaria Nigeria for the Doctoral Tet fund Research support that made this research study possible.

Introduction

Since the discovery of carbon nanotubes by Ijama in 1991, a researcher with the Nippon Electric Company (NEC) Laboratory in Tsukuba, Japan (Zhao *et al.*, 2006) has been in the focus of material research due to their unique electronic and mechanical properties in combination with the chemical stability. Carbon nanotubes (CNTs) are nanostructures resulting from revolved graphene planes and have a range of attractive chemical and physical properties. CNTs exist as single (SWNTs), and multi-walled (MWNTs) structures. CNTs theoretically is well known of its high electrical conductivity, very high tensile strength, highly flexibility where it can be bent considerably without damage, very elastic $\sim 18\%$ elongation to failure, high thermal conductivity, low thermal expansion coefficient, good field emission of electrons and high aspect ratio (length to diameter ratio more than 1,000,000) (Dresselhaus *et al.*, 2000; AzoNano, 2005; Danafar *et al.*, 2009).

Hexavalent chromium (Cr^{6+}) is far more mobile than the trivalent (Cr^{3+}) chromium (Selvi *et al.*, 2001). Increased concentrations of these elements in environment prove to be toxic. The main route of chromium excretion in human body is via kidneys into urine, and via bile duct into feces. Irrespective of the manner of intake, Cr^{3+} is absorbed too a far lesser degree than Cr^{6+} . Furthermore, Cr^{6+} is highly toxic when entering through dermal contact and through respiratory tract, respectively. The hexavalent chromium $\text{Cr}(\text{VI})$ poses a threat as a hazardous metal and its removal from aquatic environments through biosorption has gained attention as a viable technology of bioremediation (Al-Homaidan *et al.*, 2018).

Conventional methods have been found to be ineffective, particularly when the metal concentrations have been in the range of 1–10 mg/L. In addition, these techniques produce immense quantities of chemicals. They are also not cheap and impractical to be used widely in low income countries. This study has been emphasized on the application of carbon nanotubes coated by activated carbon (AC) for chromium $\text{Cr}(\text{VI})$ removal from the wastewater. The significance of this study is to have a better understanding in the applications of carbon nanotubes in preserving the environment and also to hold paramount the safety, health and welfare of the society. Furthermore, this study was conducted in order to determine the optimization of the purification process of the aqueous wastewater treatment.

Malaysia is rich in water resources, receiving an annual average of 990 billion m^3 , of which 360 billion m^3 or 36 % returns to the atmosphere as evapo-transpiration, while 566 billion m^3 or 57% appears as surface runoff and the remaining 64 billion m^3 , or 7% goes to recharge groundwater. However, an overall water demand is growing at a rate of 4% annually, and is projected to be about 20 billion m^3 by 2020 (Abdullah, 1999). Quantitatively, this is less than 4% of annual runoff, but due to the variation in rainfall, some regions of high water demand are approaching the limits of readily available water and water stress has become more prevalent over the past few years, culminating in the water crisis affecting some parts of the country in early 1998. In the year 2004, Department of Environment Malaysia (DOE) has recorded 17,991 water pollution point sources in Malaysia comprising mainly sewage treatment plants (8414: 54%), manufacturing industries (8203: 38%), animal farms (904: 5%) and agro-based industries (470: 3%) (Seo *et al.*, 2003).

Furthermore, common pollutants generated by industrial activities are heavy or trace metals such as mercury, arsenic, cadmium, chromium, lead, zinc and copper. Therefore, states with high industrial development (Pulau Pinang, Johor and Perak) have high levels of heavy metal (lead and mercury) contamination (Department of Environment, 2004). The usual concentration of chromium in wastewater in Malaysia is between the ranges of 0.2–0.5 mg/l (Abdullah, 1999). There are several methods which can be used for removal of chromium from wastewater include reduction, precipitation, ion exchange and solvent extraction. However, all of these treatments are said to be high in cost and low feasibility for small scale industries. Therefore, these treatments are not widely practiced. Another method is activated carbon (AC) for the removal of heavy metals from wastewater which is more efficient and widely used technique.

Production of Carbon Nanotubes and its Coating

The production of carbon nanotubes is conducted in two horizontal tubular reactors. The horizontal reactors are a quartz tube of 50 mm in diameter and 1200 mm in length and heated by silicon carbide heating element. The catalyst was fixed at the first reaction chamber while the second reaction chamber was used for the reaction and growth processes. Two types of gases used in this system are hydrogen as a reacting gas and the argon for flushing the air from the system, and both of them were controlled by a flow meter (Chen *et al.*, 2006).

CNT Coated Activated Carbon

For the growth of carbon materials on the surface of the AC, an impregnation process was conducted first. The function of impregnation is to fix the catalyst on the activated carbon at nanoscale level which is then known as nanocatalyst. The method

Table 1 Experimental parameters and its variation

No.	Parameter	Variation		
		Low	Medium	High
1.	Concentration of chromium (mg/L)	0.2	0.35	0.5
2.	Adsorbent dosage (mg/50 mL)	Fixed		
	Normal activated carbon	2	11	20
	Activated carbon coated with carbon nanotubes (Type I)	2	11	20
	Activated carbon coated with carbon nanotubes (Type II)	2	11	20
3.	pH	2	3	4
4.	Time contact (min)	60	150	240
5.	Agitation speed (rpm)	100	150	200

which is used for the growth is wet impregnation where the AC is condensed in the solution. The activated carbon (AC) used for impregnation was pre-washed with nitric acid to remove the inorganic impurities. The AC particle size used is $<50\ \mu\text{m}$. The catalyst salt which has been used in this method is $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ from Aldrich, AR grade. Then, $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ is dissolved in acetone at a certain amount to reach 1 wt% Ni.

For the wet impregnation, the metal precursor ($\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$) was dissolved in 10 ml of acetone and was mixed with the AC support at 25°C under ultrasonic bath for 30 min. The samples were dried at 60°C for 12 h. This step is to create a small Ni catalyst in nanoscale size over the activated carbon as mentioned earlier. After that, the samples were then calcined with O_2 or N_2 at small flow rate in order to change $\text{Ni}(\text{NO}_3)_2$ to NiO and then it has been reduced to Ni by reduction reaction with H_2 before carbon growth in a tubular furnace. The samples are referred Ni/AC-WI. The filamentous carbon was synthesized in tubular quartz reactor at 700°C for 1 h in a mixture of 30 ml/min ethylene and 200 ml/min H_2 flow rate (Chaisitsak *et al.*, 2004).

Adsorption of Chromium

Batch mode adsorption studies has been carried out by taking 50 ml of chromium aqueous solution of the desired concentration (0.2–0.5 mg/l) and desired weight of AC in 100 ml conical flasks. By using the chromium aqueous solution, the optimization of the experimental conditions has been observed. Thus, this is the reason for using chromium aqueous solution instead of wastewater sample. The chromium sample has been prepared by dissolving a known quantity of potassium dichromate ($\text{K}_2\text{Cr}_2\text{O}_7$) in deionized water. The working solutions were prepared by diluting the stock solution with distilled water. Then, the conical flasks were agitated at desired speed using a mechanical shaker. The pH was also adjusted by using 0.1 N sulfuric acid or 0.1 N sodium hydroxide (Yang *et al.*, 2015).

After the desired equilibrate time, the adsorbent and adsorbate have been separated by vacuum filtration and the filtered solution was analyzed by HACH-DR/2400 spectrophotometer with 1,5 diphenyl carbazide at 543 nm. Then, the effects of dosage of AC, the initial concentration of chromium, pH, time contact and the agitation speed have been studied. All of the experiments were carried out in duplicate and mean values have been calculated.

Table 1 showed the experimental parameters and its variation which was used in the batch mode adsorption experiment. The run orders for complete randomized experiment have been determined by using MINITAB fractional factorial design software. Fractional factorial designs are useful in factor screening because they reduce down the number of runs to a manageable size. The runs that are performed are a selected subset or fraction of the full factorial design.

Results and Discussion

The growth mechanism of CNTs concerned decomposition of ethylene molecules into hydrogen and carbon, dissolution of the carbon phase into metal catalyst particles and redeposition of the carbon atoms on the surface of the catalyst. The quality of CNTs was accessed by manipulating the temperature, catalyst type and composition, size of the iron particles and support material. The morphology of filamentous carbon grown was observed by field emission scanning microscopy, FESEM (JEOL JSM-6700F). Platinum coating has been used prior to the FESEM observation. The diameter of the carbon nanotubes has been obtained and the surface of the adsorbents has been observed.

Adsorption Capacity on Cr Removal

The influence of several operational parameters including the dose of adsorbent, agitation speed, initial pH, initial chromium concentration and contact time was investigated for maximum yield and crystallinity of nanotubes. The results were expressed as

Fig. 1 C_e/Q_e vs. C_e for normal activated carbon.

the adsorption capacity, (mg/g) of the adsorbent on chromium removal which was defined as

$$q_t = \frac{(C_o - C_t)V}{m_s} \quad (1)$$

where:

C_o , and C_t are the Cr(VI) concentrations in mg/L initially and at a given time t , respectively.

V is the volume of the Cr(VI) solution in ml.

m_s is the weight of activated carbon in g.

The removal efficiency (E) of the adsorbent on Cr(VI) ions in solution was calculated using Eq. (2):

$$E(\%) = \left[\frac{(C_o - C_t)}{C_o} \right] \times 100 \quad (2)$$

Adsorption isotherms have been used to determine or examine the relationship between the sorbed (Q_e) and the aqueous concentration (C_e) at equilibrium. In this study, Langmuir and Freundlich equations have been selected since these two sorption isotherms models are most widely used. The Langmuir and Freundlich equations were used to describe the data derived from the adsorption of Cr by each adsorbent over the entire operational parameters range studied. The Langmuir model assumes that the uptake of metal ions occurs on a homogenous surface by monolayer adsorption without any interaction between adsorbed ions $S_v + A \leftrightarrow S.A$, where S_v is vacant adsorption site on adsorbent in mole/L adsorbent, A is adsorbate in solution (mole/L Solution), S.A is Adsorbate bound to adsorbent site (mole/m²).

$$\text{At equilibrium } K_{ad} = [S.A]/[S_v][A] \quad (3)$$

Consider total number of sites, S_T , to be fixed: (possible if monolayer coverage is assumed).

$$S_T = [S_v] + [S.A] \text{ (moles/m}^2\text{)} \quad (4)$$

Combining Eqs. (3) and (4)

$$S_T = [S.A]/K_{ad}[A] + [S.A] \quad (5)$$

Solve for $[S.A]$ and use $C_A = [A]$

$$[S.A] = S_T /$$

while, Freundlich model is an empirical equation based on adsorption on a heterogeneous surface (Dow, 1995).

Therefore, from the batch mode experimental data obtained and by using Langmuir equation, the plot of C_e/Q_e versus C_e for each adsorbent has been developed. Figs. 1–3 showed the plot of Langmuir model for normal activated carbon, activated carbon coated with carbon nanotubes (type I) and activated carbon coated with carbon nanotubes (type II) respectively. The slope $\frac{1}{X_m}$ and intercept $\frac{1}{X_m K}$ has been determined from the linearized formed of the Langmuir equation as shown in Table 2. The X_m values obtained from the slope of the graph indicates the constant related to the area occupied by a monolayer of adsorbate which reflecting the adsorption capacity.

For Freundlich model, a plot of $\ln Q_e$ versus $\ln C_e$ which enables the constant $1/n$ and K_f to be determined has been developed and the value for each $1/n$ and K_f is shown in Table 2. Figs. 4–6 showed the plotted graph for normal activated carbon, activated carbon coated with carbon nanotubes (type I) and activated carbon coated with carbon nanotubes (type II) respectively. The K_f value obtained from the Freundlich equations indicates the constant of the relative adsorption capacity of the adsorbent.

All of the figures shown below are the plotted graphs for Langmuir and Freundlich equations for each adsorbent used in the batch mode experiment. The values listed in Table 2 were obtained from these plotted graphs.

Using Langmuir model, it has been noted that activated carbon coated with carbon nanotubes (Type I) has the highest adsorption capacity of 11.574 mg/g followed by activated carbon coated with carbon nanotubes (Type II) and normal activated carbon. It has been calculated that activated carbon coated with carbon nanotubes adsorb 23.7% more compared to normal activated carbon. Similar observation of Freundlich model where activated carbon coated with carbon nanotubes (Type II) has the

highest adsorption capacity of 8.4697 mg/g followed by activated carbon coated with carbon nanotubes (Type I) and normal activated carbon. It is also shows that activated carbon coated with carbon nanotubes has an adsorption capacity of 28.7% more than the normal activated carbon.

Comparison of Langmuir and Freundlich isotherms, Langmuir isotherms have a higher fitting model than Freundlich as the former have higher correlation regression coefficient than the latter as shown in [Table 2](#). Therefore, this indicates the applicability of monolayer coverage of the Cr (VI) on the surface of the adsorbent. This is due to the fact that, activated carbon has a small surface area for metal adsorption ([Nomanbhay and Palanisamy, 2005](#)). Therefore, only monolayer adsorption occurred on its surface.

In conclusion, the usage of activated carbon coated with carbon nanotubes as an adsorbent give a high adsorption capacity compared to normal activated carbon. This is due to the large surface area provided by the carbon nanotubes attached to the activated carbon surfaces. Thus, it increased the ability of the adsorbent to adsorb more chromium ions from the solution. From the adsorption isotherms analysis, it has been found that Langmuir isotherms gives higher correlation on the regression coefficient compared to Freundlich isotherms due to the reasons discussed earlier.

Regression Analysis on Adsorption Capacity

Regression equations for each adsorbent have been developed by using Minitab Release 14 statistical software.

$$\begin{aligned}
 Y = & \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \beta_5 x_5 + \beta_{11} x_1^2 + \beta_{22} x_2^2 + \beta_{33} x_3^2 + \beta_{44} x_4^2 + \beta_{55} x_5^2 \\

β_{134} , β_{135} , β_{234} , β_{235} , β_{345} , interaction coefficients. It is also important to note that, x_1 , x_2 , x_3 , x_4 and x_5 are the independent variables which are known as the initial chromium concentration, adsorbent dosage, pH, time contact and agitation speed respectively.

The results for each regression analysis are shown in the MINITAB Output Box. MINITAB Output **Tables 3** and **4** shows the regression output box developed by MINITAB statistical software package for the regression analysis for normal activated carbon, activated carbon coated with carbon nanotubes (Type I & II) respectively. The print out MINITAB output is produced by following the command path *Stat>Regression* (includes a section labeled 'Analysis of Variance').

Regression analysis for normal activated carbon

The regression analysis for normal activated carbon has been done by analyzing both primary variables and also two factors interaction variables. **Table 3** shows the output obtained from MINITAB.

As a result, the regression equation comprising all the explanatory variables for normal activated carbon analysis is as follows:

Adsorption capacity, (mg/g) = 25.3 - 28.5 Cr Conc. - 0.0720 Adsorbent Dose - 0.548 pH - 0.058 Time Contact + 0.00827 Speed + 0.165 Cr Conc. * Adsorbent Dose + 0.00119 Adsorbent Dose * pH - 0.000019 Adsorbent Dose * Speed

By referring the MINITAB Output Box **Table 3**, the third column "T" and fourth column "P" of the output indicates the test statistics and significant P values respectively. Therefore, the significance of the parameters included can be identified. The larger the magnitude of t-test value and smaller the p-value indicates the high significance of the corresponding coefficient (*Al-Homaidan et al., 2015*). From **Table 3**, t-table with α -value to be 0.025 and degree of freedom equal to 17, the critical value of 't' is 2.1098 has been determined.

From the output, it has been noted that the t-ratios for all parameters are above the t-critical value and small p-values which is less than 0.05, thus all of the parameters are said to be significance to the response variable except for the interaction variable between adsorbent dosage and speed with t-ratio less than the t-critical value and high p-value ($p > 0.05$). From the t-ratios also, it has been identified that adsorbent dosage and contact time are highly significant followed by the interaction variables between initial chromium concentration and pH which also gives a significant value to the response variable.

The coefficient of determination, R^2 has been determined to be 0.99 which means 99% of the variation in adsorption capacity can be explained by the initial chromium concentration, adsorbent dosage, pH, time contact and also speed of mixing. However, the adjusted R^2 obtained is 98.2% of the variation in the adsorption capacity. This adjusted R^2 value is necessary when comparing two or more regression models that predict the same dependent variable but have different numbers of explanatory variables (*Dow, 1995*). By using this adjusted R^2 value, the best model can be identified.

Regression analysis for activated carbon coated with carbon nanotube (Type I)

The result of regression analysis for activated carbon coated with carbon nanotubes is shown in the MINITAB Output Box [Table 4](#) below. It has been analyzed from both primary and 3 factors interaction variables.

The adsorption analysis has been extracted from regression equation analysis to describe the data is as follows:

Adsorption Capacity, (mg/g) = 28.3 - 33.2 Cr. Conc. - 0.0493 Adsorbent Dose - 0.056 pH - 0.0748 Time Contact + 0.00564 Speed + 0.00059 Cr Conc. * Adsorbent Dose * pH + 0.000575 Cr Conc. * Adsorbent Dose * Time Contact - 0.000051 Cr Conc. * Adsorbent Dose * Speed

From the t-ratios in the MINITAB output box [Table 4](#), shows that there are some of the parameters are highly significant but there are also not significant to the response variable. For an instant, in this study the t-ratios of pH, speed, interaction variables of initial chromium concentration, adsorbent dosage and pH and interaction variables of initial chromium concentration, adsorbent dosage and speed are less than the t-critical value 2.1098 and therefore they are not significant to the adsorption capacity. The observation to the significant P-value stated earlier is greater than 0.05.

Therefore, for this type of adsorbent it has been noted that the parameters which are significant to the adsorption capacity are the initial chromium concentration, adsorbent dosage and also the time contact of the batch mode experiment. However, from the analysis the t-ratio of the adsorbent dosage gives the highest value compared to others which determines that it is highly significant to the response variables. Then the significance levels are followed by the time contact and the initial chromium concentration.

The coefficient of determination which is the square of the coefficient of correlation, R^2 is 98.6% which means that 98.6% of the variation in adsorption capacity can be described for by all explanatory variables and the adjusted R^2 value obtained in this analysis is 97.3%. The values for R^2 and adjusted R^2 obtained from activated carbon coated with carbon nanotubes (Type I) regression analysis are lower than the values of the coefficient of determination obtained from the normal activated carbon analysis.

Regression analysis for activated carbon coated with carbon nanotube (Type II)

The regression output obtained from MINITAB software is shown in the Output Box [Table 5](#) below. The analysis has been done by both primary and 3 factors interactions explanatory variables.

Table 5 MINITAB output box regression analysis for activated carbon coated with carbon nanotubes (Type II)

The regression equation is					
Adsorption Capacity, (mg/g) = 40.3 - 45.5 X1 - 0.0674 X2 - 0.754 X3 - 0.101 X4					
+ 0.00285 X5 + 0.00648 X1X2X3 + 0.000734 X1X2X4					
- 0.000080 X1X2X5					
Predictor	Coef	SE Coef	T	P	
Constant	40.284	4.141	9.73	0.000

X1X2X4	0.00073380	0.00009075	8.09	0.000	
X1X2X5	-0.00008038	0.00003110	-2.58	0.029	
S = 0.294038 R-Sq = 99.5% R-Sq(adj) = 99.0%					
Analysis of Variance					
Source	DF	SS	MS	F	P
Regression	8	148.424	18.553	214.59	0.000
Residual Error	9	0.778	0.086		
Total	17	149.202			

The regression equation embracing all the explanatory variables obtained from the regression analysis done by MINITAB is as follows:

Adsorption Capacity (mg/g) = 40.3 - 45.5 Cr Conc. - 0.0674 Adsorbent Dose - 0.754 pH - 0.101 Time Contact + 0.00285 Speed + 0.00648 Cr Conc. * Adsorbent Dose * pH + 0.000734 Cr Conc. * Adsorbent Dose * Time Contact - 0.000080 Cr Conc. * Adsorbent Dose * Speed

By referring the t-ratios obtained from the analysis, it shows that some of the explanatory variables are highly significant and some of the parameters are significant to the response variable. However, the speed of mixing during the experiment is not significance to the adsorption capacity due to the t-ratio and the p-value for this primary variable are 1.23 and 0.251 respectively. The t-ratio is less than t-critical value 2.1098 and the p-value for this parameter are larger than 0.05.

Specifically, the explanatory variables which are highly significant to the adsorption capacity of the adsorbent are the initial chromium concentration, adsorbent dosage, pH, time contact, interactions between initial chromium concentration, adsorbent dosage and pH, interactions between initial chromium concentration, adsorbent dosage and time contact and also interactions between initial chromium concentration, adsorbent dosage and speed of mixing during the experiment.

The coefficient of determination, R^2 obtained from the regression analysis for the activated carbon coated with carbon nanotubes (Type II) is 99.5% which very high compared to other regression model. 99.5% of the variation in adsorption capacity can be accounted for by the explanatory variables. The adjusted R^2 obtained for this regression analysis is 99.0%. The adjusted R^2 value for this regression model is higher than other regression models for different types of adsorbent. Therefore, it can be concluded that this regression model is the best model compared to others due to the adjusted R^2 value.

Effect of Process Variables on Adsorption Capacity

Effect of pH

The pH is also said to be an important parameter for the adsorption of metal ions from aqueous solution because it affects the solubility of the metal ions, concentration of the counter ions on the functional groups of adsorbent and the degree of ionization of the adsorbate during the reaction. The removal of chromium by three types of adsorbents with various pH has been studied. The variations of pH used in the experiments are within the range of 2–4. It has been reported that the variation in adsorption capacity in this pH range is largely due to the influence of pH on the adsorption characteristic of the adsorbents used (Nomanbhay and Palanisamy, 2005). This is due to the highly protonated adsorbent surfaces and also the uptake of the free ionic Cr. Therefore, with

Table 6 Effect of pH due to the coefficient of determination, R^2 values for various adsorbents used in the removal of chromium

Adsorbent type	R^2 (%)	Adjusted R^2 (%)
Normal activated carbon	1.0	0.0
Activated carbon coated with carbon nanotubes (Type I)	0.5	0.0
Activated carbon coated with carbon nanotubes (Type II)	0.1	0.0

Table 7 Effect of time contact due to the coefficient of determination, R^2 values for various adsorbents used in the removal of chromium

Adsorbent type	R^2 (%)	Adjusted R^2 (%)
Normal Activated Carbon	8.0	2.2
Activated Carbon coated with Carbon Nanotubes (Type I)	5.6	0.0
Activated Carbon coated with Carbon Nanotubes (Type II)	7.9	2.1

Table 8 Effect of speed due to the coefficient of determination, R^2 values for various adsorbents used in the removal of chromium

Adsorbent type	R^2 (%)	Adjusted R^2 (%)
Normal activated carbon	0.5	0.0
Activated carbon coated with carbon nanotubes (Type I)	0.2	0.0
Activated carbon coated with carbon nanotubes (Type II)	0.0	0.0

increasing pH from 2 to 4 was decrease the degree of protonation of the surface and reduced the adsorption capacity of the chromium. The optimum pH which has been observed during the experiments with 100% Cr(VI) removal is at pH 2.0.

However, from the regression model developed, the value of adjusted R^2 for each adsorbent shown in **Table 6** gives a zero value. Although the values of R^2 is very small, there is no reason to reject the model since it has been clearly stated that pH affects the adsorption capacity as discussed earlier.

Effect of time contact

The variation of time contact in this study is within the range of 60–240 min. Therefore, the effect of this parameter to the adsorption capacity has been observed. It has been reported by (Karthikeyan *et al.*, 1996; Levine *et al.*, 2001) that the removal efficiency of chromium increased with an increased in contact time. From regression analysis also denotes that the time contact during the experiments is highly significance with the adsorption capacity for the three adsorbents used. However, the regression model specifically for the time contact which has been developed by selecting the time contact as the predictor variable gives a small value for both R^2 and adjusted R^2 for each adsorbent as seen in **Table 7**. Despite the small R^2 in this model, it has been clear that the adsorption capacity is dependent on the time contact. Therefore, rejection of this model is not necessary.

Effect of agitation speed

The effect of agitation speed on adsorption capacity of chromium has been studied by varying the speed of agitation from 100 to 200 rpm. It has been said that the percentage of chromium removal increased with increasing agitation speed. From the regression model which has been developed, it is clearly stated that the speed of mixing during the batch adsorption experiment is significant to the removal of chromium using normal activated carbon p-value is less than 0.05 as in **Table 8**. This is due to the fact that, the increase of agitation speed, improves the diffusion of chromium ions towards the surface of the adsorbents. However, it is not significance to the adsorption by using activated carbon coated with carbon nanotubes type I and type II. The regression analysis which has been done specifically for this parameter also shows very small R^2 and adjusted R^2 .

Optimization of Process Variables for Removal of Chromium

As discussed earlier, the batch adsorption experiment which has been done was completely randomized by MINITAB fractional factorial design. The optimum condition has been determined from the tabulated results of adsorption capacity. The adsorption capacity for each experiment has been calculated and has been listed in **Table 9** for the three types of adsorbents which are normal activated carbon, activated carbon coated with carbon nanotubes type I and activated carbon coated with carbon nanotubes type II respectively. The predictive values of the adsorption capacity have been determined from the regression equation obtained. From

Table 9 The parameters condition for optimum adsorption capacity (mg/g) obtained from each adsorbent used

<i>Adsorbent type</i>	<i>Chromium conc. (mg/l)</i>	<i>Adsorbent dosage, m (mg/50ml)</i>	<i>Adsorbent dosage, m (mg/L)</i>	<i>pH</i>	<i>Time contact (min)</i>	<i>Agitation speed (rpm)</i>	<i>Cr remaining, c (mg/L)</i>	<i>Cr removed, x (mg/l)</i>	<i>% Cr removed</i>	<i>Predictive adsorption capacity, (mg/g)</i>	<i>Experimental adsorption capacity, x/m (mg/mg)</i>
Normal activated carbon	0.5	2	40	4	60	200	0.17	0.33	66.0	7.49	8.250
Activated carbon coated with carbon nanotubes (Type I)	0.5	2	40	4	60	200	0.23	0.27	54.0	6.68	6.750
Activated carbon coated with carbon nanotubes (Type II)	0.5	2	40	2	60	100	0.14	0.36	72.0	8.551	9.000

this tabulated results, the optimum conditions for each parameters have been identified and highlighted. The optimum conditions are determined from the highest value of adsorption capacity, (mg/g) of the chromium concentration. The parameters conditions which contributes to the optimum adsorption capacity for each adsorbents used are shown in Table 9.

From the experimental results obtained, the optimum parameters for each adsorbent are dependent on the adsorbent characteristics. The values for each parameter used might be similar and it might vary in order to obtain a maximum adsorption capacity. From Table 9, it has been noted that in order to obtain an optimum value of adsorption capacity, the optimized value for the initial chromium concentration should be 0.5 mg/L with adsorbent dosage of 2 mg in 50 ml solution and it requires 60 min contact time between the adsorbent and the solution for each type of adsorbent studied.

However, the optimized pH for the normal activated carbon and activated carbon coated with carbon nanotubes type I should be at pH 4 which is different to the activated carbon coated with carbon nanotubes type II adsorbent where the optimized pH value for this particular adsorbent should be at pH 2. Furthermore, the agitation speed for activated carbon coated with carbon nanotubes type II is 100 rpm which is also varies with optimized agitation speed obtained for the normal activated carbon and activated carbon coated with carbon nanotubes type I which is said to be 200 rpm. From the tabulated result, the activated carbon coated with carbon nanotubes type II gives the highest value of adsorption capacity with 9.0 mg/g compared to the normal activated carbon and the activated carbon coated with carbon nanotubes type II which are 8.25 and 6.75 mg/g respectively. In conclusion it is clearly confirmed that the activated carbon coated with carbon nanotubes type II gives high adsorption capacity of the chromium concentration within the minimum parameters variation as listed in Table 9.

Conclusion

CNT materials were produced in two horizontal tubular reactors by using different catalyst weights and process temperatures. The formation of dense MWCNT was confirmed through microscopic analysis. The application of carbon nanotubes in removal of chromium from aqueous wastewater have been done in environmental field. In this study, three adsorbents have been used in the study of chromium removal from aqueous wastewater which comprised of normal activated carbon, activated carbon coated with carbon nanotubes type I and II. By comparing these three adsorbents, the efficiency of the adsorption has been determined. There are 5 factors which were said to be contributing the adsorption capacity in the experiment have been studied and the optimized conditions for each parameter have been identified. The initial chromium concentration, adsorbent dose, pH, time contact and the agitation speed are the factors which have been studied. The values for each parameter are completely randomized throughout the designed experiment as discussed earlier. All of the factors used in the adsorption experiment were said to be significance with the adsorption capacity which has been identified from the regression analysis.

Study has been proven that the activated carbon coated with carbon nanotubes as an adsorbent is a good candidate for adsorption of chromium ions and promisingly to be a good candidate for adsorption of other heavy metal ions as well. Hopefully, this study gave an enormous impact on the development of wastewater treatment and the development of nanotechnology applications.

Introduction

Residual stress may be defined as the self-equilibrating internal stress existing in a free body under uniform temperature conditions without any external load or thermal gradient. At equilibrium both the resultant force and the resultant moment of the body are zero. It is most commonly termed as the “residual stress” as it may be “left over” by a previous manufacturing process. Macherauch and Kloos (1986) suggested a classification of residual stress into three groups, as shown in Fig. 1, using the term “homogeneous” to mean “constant in magnitude and direction” as:

- (1) Type I – Macro residual stresses which are homogeneous across several grains of the material and are equilibrated over the body.
- (2) Type II – Nearly homogeneous micro residual stress which are homogeneous only on a part of a grain or one grain and equilibrated over several grains. Such stresses may exist in single-phase materials due to anisotropy in the behavior of each grain or develop in multi-phase materials due to the different properties of different phases.
- (3) Type III – Inhomogeneous micro residual stresses which are inhomogeneous even over sub-microscopic distances inside the body but in equilibrium on small parts of a grain due to the existence of dislocations and other crystalline defects.

One or a superposition of these three categories defines all the residual stress states. However, from an engineering perspective the first category has more importance than the other two since any modification to equilibrium may also modify the external dimensions of the body. Residual stresses arise from a number of sources and can exist in the unprocessed raw material, during manufacturing processes involving material deformation, heat treatment, machining or processing operations which transform the shape or change the properties of a material or can also arise from in-service loading (Withers and Bhadeshia, 2001a).

Welding process commonly generates residual stresses in engineering structures and components which are the key factor in the structural integrity assessment. It is thought that reheat cracking in plant structures is solely driven by the presence of residual stress field (Baikie *et al.*, 1997; Dhooze, 1998; Skelton *et al.*, 2003). Compressive residual stresses can help to restrain crack propagation and enhance fatigue life and therefore, can have a beneficial effect on structural integrity. In contrast, tensile residual stresses in general have an adverse effect on brittle fracture, corrosion properties and fatigue performance. With residual stress levels reaching the material yield strength, the consequence of residual stress effects on structural integrity become substantial. Reliable technique to correctly analyze these residual stresses can help move away from decade old over conservative structural integrity assessment and is a key to an accurate and sustainable structural integrity assessment.

Residual Stress Measurement Methods

Strains rather than stresses are invariably measured by residual stress measurement methods. The measured strains can be used to deduce the residual stresses through a simple elastic relation using the appropriate material elastic constants including the Young's

Fig. 1 Classification of residual stresses according to length scales. After Kandil, F.A., Lord, J.D., Fry, A.T., Grant, P.V., 2001. A review of residual stress measurement methods – A Guide to Technique Selection. NPL Report MATC (A) 04.

modulus, E and the Poisson's ratio (ν). A single value of the stress is often quoted instead of its distribution and is assumed to be constant within the measurement volume. When measured residual stresses by different techniques are compared, the sampling volume and the resolution of each measurement method are considered in relation to the type of residual stress being measured (see Fig. 1), in particular if type II and III micro stresses are of interest (Kandil *et al.*, 2001). The concept of the characteristic volume is also considered essential. It is the volume over which a given type of residual stress averages to zero. Most material removal techniques, e.g., the hole drilling method, layer removal method remove large volumes of material over which type II and III stresses average to zero and only the macro residual stresses remain and are measured.

Residual stress measurement methods range from non-destructive technique via semi-destructive to the fully destructive technique. Non-destructive technique includes the diffraction, magnetic and ultrasonic techniques. Semi-destructive techniques where the component is partially damaged and does not compromise its integrity include the incremental center-hole drilling technique and the deep-hole drilling technique. In the destructive technique the component is destroyed completely and includes the Sachs method (Sachs, 1927; Garcia-Granada *et al.*, 2000) and the curvature and the layer removal method (Treuting and Read, 1951; Withers and Bhadeshia, 2001b). Here a description of the mechanical strain relief deep-hole drilling method is reviewed due to its relevance to the present study.

Deep-hole drilling (DHD) method measures residual stresses in thick components. A schematic illustration of the method is provided in Fig. 2. A small reference hole is drilled through the component and the diameter $d(\theta, z)$ of the hole is measured along its depth. A cylindrical column (core) of material concentric to the reference hole is then removed from the component, using a trepanning technique. This causes the stresses in the cylindrical core to relax and change the reference hole diameter and column dimensions. The dimensions of the column and reference hole diameter $d'(\theta, z)$ are re-measured. The dimensional changes caused by removing the material from the bulk of the specimen are then used to calculate the residual stresses.

The method was originally developed by Zhdanov and Gonchar (1978) and Beaney (1978). Zhdanov and Gonchar (1978) measured residual stress in steel welds by drilling 8 mm diameter hole followed by an incremental cutting of a concentric column of metal of 40 mm diameter from the specimen using a hollow drill. By using changes in the axial length during incremental trepanning and measuring the diameter changes in two mutually perpendicular directions at a number of fixed distances along the reference hole they measured the residual stresses in the component.

Beaney's (1978) approach to the measurement procedure was to gun-drill a very smooth and straight hole of diameter 3.175 mm along the direction of a principal stress component and to measure its diameter at three in-plane angles of 0° , 45° and 90° at every 2 mm depth along the reference hole. In his approach, he measured the hole diameter first using strain gauges fixed onto two parallel beams fixed together and drawn along the sidewalls of the hole. By using the strain gauges the changes in diameter were measured due to the trepanning of the core by electro-chemical machining (ECM) process which allows to measure the beam deflection.

A substantial development of the technique has undergone over the past two decades mainly at University of Bristol (Bonner and Smith, 1994; Smith and Bonner, 1996; George *et al.*, 2000; Smith *et al.*, 2000; Hossain *et al.*, 2017) both in the improvement of the method (e.g., using air-probe to measure the hole diameter) and its accuracy. George *et al.* (2002) used small holes to measure stresses in calibration of aluminum and steel samples arising from external applied loading.

The technique was further developed by using smaller hole and smaller core which improved the precision of the measured stresses. Measurements of diametral distortions at higher number of angles, i.e., 18 angular measurements substantially reduced the error associated with the air-probe measurements. Other advancement includes the design of a small-scale portable deep-hole drilling rig (Kingston, 2004; Ficquet, 2007) capable of measuring residual stresses in metal parts of depths in the range of 5–500 mm.

George (2000) used finite element analysis (FEA) to model a pipe under autofrettage and compared the predicted FEA residual stress distribution with the stress distribution measured using deep-hole drilling (DHD) and Sachs methods. By considering removal of elements which defined drilled reference hole and electric discharge machining (EDM) thickness, he further modelled and simulated the deep-hole drilling of the autofrettaged tube. He found that the predicted FEA simulated DHD residual stresses compared well with the stresses measured by the DHD method. In his DHD FEA analysis, he removed the set of elements defining

Fig. 2 Schematic of the DHD method: Step 1 – Drilling a reference hole, step 2 – Measuring reference hole diameter, step 3 – Trepanning a core and step 4 – Re-measuring reference hole diameter.

the EDM thickness, i.e., the material which is machined away during the trepanning stage in a single step. However, in practice the trepanning process takes place incrementally so that the removal of elements defining the EDM thickness needs to be carried out incrementally in order to model the trepanning process more realistically.

Residual Stress in Structural Integrity

Residual stresses have influence on the life assessment of engineering structures. Manufacturing process and final fabrication may generate residual stresses. Tensile residual stresses generally have detrimental effect on life of engineering components. The presence of residual stress can solely initiate cracking even in the absence of service loads. When the component enters into service, tensile residual stress combines with service stresses and reduces crack-initiation time and accelerates growth rates of pre-existing or service-induced defects. Welding is a common manufacturing process where residual stresses can reach the level of yield stress. Post-weld heat treatment is usually applied to reduce such stress level. One of the reasons for residual stresses to develop in engineering components is the presence of repair welds. Fabrication defects in castings or welds, or in-service degradation of components which can be treated or improved by applying repair welds and thereby extend the life and economic operation of ageing engineering plant. Repair weld can be applied to a localized shallow excavation using standard weld procedures or to deep excavations covering a significant proportion of the structure. Weld metal failing to fuse completely with the sidewall of the joint lead to sidewall fusion defects. The need to rectify these defects or degraded heat affected zone (HAZ) material typically leads to repairs that are offset from the weld centerline. A survey of weld repair technologies used by electric power research institute (EPRI)

Fig. 3 Arrangement of stainless steel pipe girth weld with repair weld, dimensions in mm. Reproduced from Hossain, S., 2005. Residual stresses under conditions of high triaxiality. PhD Thesis. UK: University of Bristol.

member utilities (Candy *et al.*, 2001) has found that 40% of all repairs to steam chests, piping and headers resulted in subsequent cracking. This was thought to be due to the high level of residual stresses associated with repair process performed without implementing post-weld heat treatment.

Hole drilling (incremental center-hole drilling) and X-ray diffraction techniques are the most widely applied methods to determine the residual stresses in engineering components. However, these methods only provide near surface residual stresses. In order to accurately assess the structural integrity of a component, a good description of the through thickness residual stress distribution along the depth of the component is required. Deep-hole drilling method is a practical means of measuring residual stresses deep into metal parts, e.g., 500 mm deep into steels (Kingston, 2004), whereas the non-destructive neutron diffraction method suffers from limitation in penetrative depth, cost and the availability. Deep-hole drilling residual stress measurements were carried out on a number of 316 H stainless steel mock-up components (George *et al.*, 2002) provided by British Energy Generation Ltd, including information on their fabrication history. Previous studies (Hossain, 2005; Mahmoudi *et al.*, 2009; Hossain *et al.*, 2011a; Zheng *et al.*, 2017) highlighted that the DHD measurement of highly triaxial residual stresses can be problematic due to the redistribution of the stresses during the strain relaxation. A numerical study of the deep-hole drilling process was undertaken to explore how the stress triaxiality and the redistribution influence the deep-hole measurement technique.

Material and Test Specimen

The test specimen consisted of a stainless steel cylindrical pipe girth weld with repair weld. Detail of the fabrication history is available in (Mitsui Babcock Report 316, 2002). Fig. 3 shows the global dimension of the test component. The length included 1022 mm, with outer diameter about 432 mm and wall thickness varying between 32 and 39 mm around the pipe. A 2.4 mm diameter wire tungsten inert gas (TIG) root was used to produce a girth butt weld near the mid-length of the pipe, followed by 16 manual metal arc (MMA) passes with an average girth weld heat input of 2.2 kJ/mm using 2.5, 3.2, 4, and 5 mm diameter electrodes. Further detail of the weld is provided in Hossain *et al.* (2006). By grinding at a location 180°, a repair cavity, 218 mm long at the outer surface of the cylinder, 26 mm deep, 7 mm offset from the girth weld centerline, with sidewall and end run-out angles of 15° and 45° respectively, was excavated. The repair excavation was filled with 14 MMA passes with heat input of 2.1 kJ/mm combining 3.2 mm and 5 mm diameter electrodes. Welding was intentionally carried out in a single direction, in order to maximize the superposition of start and stop effects. The repair cap was ground flush following welding.

The locations of the DHD measurement in the offset repair included Hole 1 which was located at the intersection of the centerline of the girth weld and the mid-length of the repair, and Hole 2 which was located at the intersection of the girth weld centerline and the stop end of the repair (Hossain *et al.*, 2006).

Weld Residual Stress

Fig. 4 shows through-thickness variation of the measured residual stresses at the locations, Hole 1 (mid-length) and Hole 2 (end position). Fig. 4(a) shows the longitudinal component and Fig. 4(b) shows the transverse component of the weld residual stresses. Also shown are the finite element predictions of the weld residual stress distribution. A reasonably good correlation existed between the measured and the prediction particularly for the transverse component of stress (Fig. 4(b)). For the longitudinal stress component (Fig. 4(a)), although similar trend existed, the FEA prediction was much higher in magnitude. For example, the FEA predicted peak longitudinal stress component was almost 300 MPa higher than the measured, giving an error of approximately 50%. In contrast, the error in the measured stresses in steel part is estimated to be ± 30 MPa (George *et al.*, 2002). Thus, the measured result in Fig. 4(a) cannot be acceptable and is further explained below.

Fig. 4 Measured residual stresses in a 218 mm long, offset, 316 H stainless steel repair weld compared with 3D FEA predictions.

(a) Longitudinal and (b) Transverse. Reproduced from Hossain, S., Truman, C.E., Smith, D.J., Bouchard, P.J., 2006. Measurement of residual stresses in a type 316H stainless steel offset repair in a pipe girth weld. *Journal of Pressure Vessel Technology*, Transactions of the ASME 128 (3), 420–426.

When measuring residual stresses using mechanical strain relief method in components containing highly triaxial residual stress field close to yield extra caution have to be exercised since the introduction of a free surface, created as part of the measurement procedure, can lead to plastic redistribution of the residual stress field. Under normal cases the plastic redistribution is not accounted for in the elastic inversion algorithms of the experimental procedure. The FEA predicted longitudinal residual stress components for both mid-length (Hole 1) and end positions (Hole 2) shown in [Fig. 4\(a\)](#) are substantially high enough for plastic redistribution to occur during the trepanning stage of the deep hole drilling measurement.

Influence of Plastic Redistribution in DHD Procedure

The influence of trepanning step on the DHD measured result was verified by [Hossain et al. \(2011a\)](#). They carried out a FEA simulated DHD procedure on repair welded pipe. The methodology and sequence consisted of four steps. (1) FEA simulation of weld residual stress field conducted by British Energy Generation Ltd (BEGL). (2) The BEGL predicted stresses were mapped onto a mesh which allowed DHD measurement simulation. (3) The FEA DHD measurement simulation was carried out. (4) The FEA simulated DHD reconstructed residual stress distribution was compared with the previously measured stress distribution.

[Fig. 5](#) shows the 3D quarter model (University of Bristol, BU model) of the welded pipe. The overall dimension and the drilling and trepanning regions are shown in [Fig. 5](#) as well. The model constructed with 14,330 quadratic brick elements has two symmetry planes including the XY (1–2) plane and the YZ (2–3) plane. As the repair was offset from the girth weld centerline, the XZ (1–3) symmetry plane did not exist. Although the short repair spans only 218 mm, i.e., covering about 16% of the circumference of the pipe, a fully circumferential repair weld was assumed in the model; the purpose of the FEA study was to investigate the influence of the plastic redistribution in the DHD measurement process on the initial residual stress. Furthermore, by using the British Energy

Fig. 6 Comparison of the residual stress distribution at the mid-length of repair weld between the measured and the FEA reconstructed using NKH model. Reproduced from Hossain, S., Goudar, D.M., Truman, C.E., Smith, D.J., 2011a. Simulation and measurement of residual stresses in a Type 316H stainless steel offset repair in a pipe girth weld. Materials Science Forum 681, 492–497.

Generation Limited (BEG) predicted weld residual stress field as initial condition for the BU model the influence of circumferential repair was minimized. Appropriate material model was constructed for parent, girth and repair weld regions, which can be found elsewhere (Hossain *et al.*, 2006).

In addition to the influence of plastic redistribution on the FEA simulated DHD result, the effect of different material hardening models was also studied. Detail of the DHD simulation and the measurement are both provided in Hossain *et al.* (2011a). Fig. 6 shows the main outcome of the study. The DHD measured residual stress distribution at the mid-length (Hole 1) of repair weld (shown in Fig. 4) is compared with the FEA simulated DHD reconstructed residual stress distribution using non-linear kinematic hardening (NKH) model. An excellent correlation exists between the FEA simulated DHD and the DHD measured residual stress distributions as shown in Fig. 6.

FEA Validation of a Modified DHD Method

In the preceding section, results from the DHD FEA simulation highlighted how the DHD process influences the measured residual stresses. In this section, a variation to the standard DHD technique, known as the over-core deep-hole drilling (oDHD) technique

(Hossain *et al.*, 2011b) developed to avoid plasticity issues is validated by utilizing FEA simulation of the technique. The influence of material removal and cutting sequence on the initial residual stress field during the DHD measurement process was explored through a 3D FEA. An FEA predicted weld residual stress field in a 40 mm thick butt-welded pipe was applied as the initial stress condition in a DHD FEA model. Detail of the FEA simulation of the weld residual stress, the standard DHD simulation and the oDHD simulation are provided in Hossain *et al.* (2011b). Fig. 7 shows the schematic of the butt-welded pipe, with outer diameter 369 mm, thickness 40 mm, and length 800 mm. Two SUSF316 stainless steel cylinders of length 400 mm each were circumferentially welded by using alloy 82 weld metal. The DHD measurement and simulation were both carried out through the weld thickness from the outer surface of the pipe.

The DHD reconstructed residual stresses are compared with the initial FEA predicted stresses in Fig. 8. Both the longitudinal and the transverse components of the stresses are shown. Close to the outer surface of the pipe, the longitudinal stresses significantly redistributes. This is attributed to the influence of plasticity during trepanning. A recently developed incremental deep-hole drilling (iDHD) technique (Mahmoudi *et al.*, 2009; Zheng *et al.*, 2017) takes into account the effect of plasticity during trepanning and provides an approximate solution to measurements of near yield residual stresses. The iDHD method has successfully been applied to various components (Hossain *et al.*, 2012; Hosseinzadeh *et al.*, 2009, 2010; Kingston *et al.*, 2010; Mahmoudi *et al.*, 2009b; Mahmoudi *et al.*, 2011; Robinson *et al.*, 2010, 2008; Zheng *et al.*, 2017). However, the iDHD method suffers from a limited spatial resolution.

In contrast, the oDHD technique (Hossain *et al.*, 2011b; Zheng *et al.*, 2017) used in the present analysis significantly improves the spatial resolution. By adding an extra step between steps 2 and 3 in the standard DHD procedure, Fig. 2 where a large core, diameter 40 mm is trepanned ensuring the initial near yield residual stress to redistribute elastically around the reference hole. Hence only elastic unloading occurs during final trepanning step 3. The choice of the over-core size depends on the specimen thickness and the cutting sequence. Zheng *et al.* (2017) studied different over-core trepan diameter to optimize the

Fig. 7 Schematic of girth-butt welded pipe. All dimensions in mm.

Fig. 8 Comparison of the standard DHD FEA reconstructed and the initial FEA predicted residual stress distribution in the butt-welded pipe. Reproduced from Hossain, S., Kingston, E., Truman, C.E., Smith, D.J., 2011b. Finite element validation of the over-coring deep-hole drilling technique. Applied Mechanics and Materials 70, 291–296.

Fig. 9 Comparison of the oDHD FEA reconstructed and the initial FEA predicted residual stress distribution in the butt-welded pipe. Reproduced from Hossain, S., Kingston, E., Truman, C.E., Smith, D.J., 2011b. Finite element validation of the over-coring deep-hole drilling technique. *Applied Mechanics and Materials* 70, 291–296.

trepan size. They found that the over-core size should be larger than both the width and depth of the welding to generate elastic stress relaxation. The size of the over-core diameter can be halved from 40 mm to 20 mm with effectively the same result to keep the destruction to the component at minimum. However, the cutting process may need to be adjusted. Therefore, a thorough FEA simulation of the oDHD procedure conducted prior to a practical measurement can provide an optimum over-core dimension.

An excellent comparison of the oDHD reconstructed residual stress distribution with the initial FEA predicted is shown in **Fig. 9**. The dimension included: Reference hole diameter 1.5 mm, over-core diameter 40 mm, final trepan diameter 15 mm. The excellent correlation between the DHD reconstructed and the initial weld residual stress validated the present oDHD technique. The integrity of the structure nominally depends on the size of the over-core relative to the size of the component structure. The application of a 40 mm diameter over-core which was small enough relative to the size of the butt-welded pipe ensured the oDHD method to remain semi-destructive.

Concluding Remarks

The accuracy in residual stress characterization on the sustainable structural integrity assessment of an engineering component has been highlighted. Two welded pipe samples were considered in the study. The DHD numerical simulation on the welded pipes indicated that the DHD technique works reasonably well for practical components. Measurements of residual stresses were made in practical components using the deep-hole drilling method and were compared with finite element prediction. In general a good correlation existed particularly for the transverse component of the residual stress. The measured distribution was generally lower than the FEA predicted. It is anticipated that a combined hardening model in the FEA study can better represent the initial weld residual stress field.

The study illustrated that a significant influence of the DHD process on the initial longitudinal residual stresses occurred; both the measured and the predicted longitudinal stress component was much higher in magnitude than the transverse component. The FEA reconstructed residual stress distribution did not provide the initial peak tensile stress close to the outer surface of the welded pipes.

The FEA study using a large over-core, diameter 40 mm (oDHD technique) illustrated that the effect of plasticity in the DHD trepanning process can be reduced without affecting the accuracy of the result. Compared to the iDHD technique the oDHD technique is much simpler to apply and can achieve residual stress data of much higher spatial resolution, the same resolution as in the standard DHD technique. The FEA DHD simulation in the butt-welded pipe validated the oDHD technique. Moreover, the study further highlighted the need to exploit an FEA study prior to practical measurements.

FDM and its Utilities for Development of Customized Materials for Maintenance

The whole world has an extraordinary and great past which is preserved in a form of heritage structures and archaeological sites. These historic heritages are the proofs of our golden history which need to be preserved for coming generations to understand its glory. Repair and rehabilitation in some defined ways are used to reconstruct or modify in order to keep their originality to represent. Repair and rehabilitation are mostly performed because of some aspects such as, deterioration due to environmental effects, new functional requirements and damages due to accidents. Epoxy injection, polyurethane injection, stitching cracks and lead flashing are some of the techniques which have been taken into consideration by the engineers for maintenance of structures (Subramaniam, 2016). Under the subject domain 'repair of heritage structures', some studies have been reported on St. Lourdes Church (Tiruchirappalli, India) for its rehabilitations and preservation of exterior surface mortar and steeple cracks. For steeple cracks maintenance, initially cleaning with soap water followed by lime mortar application for plastering has been recommended (Natarajan *et al.*, 2010). It has been reported that leakages and cracks are the mostly observed after degradations of the material used. For better understanding of degradation of material used, a study has been conducted at Nehru memorial college of K.V.G group of institutions at Mangalore, India for repair and rehabilitations of cracks found in walls. At location of cracks plastering was chipped off and V-groove was made by chiseling, water jet cleaning and cracks filling by structural grade repair mortar were performed to solve cracks issues (Pattanaik *et al.*, 2011). AM is the recent progress in the engineering fields which offers to be applicable in industrial production, civil production, aeronautics and medical implants. Additive manufacturing has the potential to be future associated technique in civil engineering field as its produced complex shapes quickly with reduced weight. Composites structures are investigated by their dynamic mechanical capabilities and thermoplastic behavior and parts produced by the additive manufacturing processes can controlled these values (Cannella *et al.*, 2017; Singh *et al.*, 2018b). AM forms the object by successive layers of materials for different application areas. 3D printing has the potential/impact to transform manufacturing supply chain, distribution channel and business model (Singh *et al.*, 2018a,b,c). There are some of the 3D printing technologies which are presently used by the society to apply as specific solutions of assembly, repair/maintenance, rapid tooling, waste management, energy storage and etc. Fused deposition modelling (FDM), stereo lithography (SLA), inkjet printing, selective laser sintering (SLS), digital light manufacturing (DLP), selective laser melting (SLM), electronic beam melting (EBM) and laminated object manufacturing (LOM) are some of the 3D printing techniques which are largely used for printing of functional/non functional prototypes (Kumar *et al.*, 2017a,b, 2018; Singh *et al.*, 2016). There are varieties of screw extrusion processes available for producing feedstock filament for FDM. Single screw extrusion is a conventional process for producing feedstock filament but defects like, tiny pores, blow holes, non-mixing are the major problems associated with this process. Twin screw extrusion has emerged as an advanced technique for producing feedstock filament free from defects. Twin-screw extruder are capable to ensure mixing, shearing, cooling, heating, compressing, transporting, shaping, pumping, etc. with very high level of flexibility. The main advantages of twin-screw extruders (intermeshing co-rotating) are their exceptional mixing capability that gives the remarkable characteristics to extruded products. In the twin-screw extrusion process, the raw materials may be solids (granules, powders & flours), slurries, liquids, and possibly gases (John *et al.*, 2014; Wang *et al.*, 2016a,b). FDM is the melt extrusion process in which robotic device is worked on the CNC programming to control the heating and movement of the filaments. The extruded material through the nozzle head is directed on the print bed and immediately hardened to ensure the part fabrication. To ensure the better dimensional stability of the component formed it is required to process the printing below the melting point of the substrate. Properties of parts produced by the FDM is the function of the filament preparations, extrusion is the basic process which are used for the preparation of feedstock filaments. Extrusion processes are largely used for the production of useful inputs for additive manufacturing techniques. The requirement of these processes is increasingly important from sustainability viewpoints when targeting waste management of thermoplastic materials. Mechanical properties of FDM fabricated parts are highly dominated by their filament processing. The mechanical sustainability of the fabricated parts is dependent on the nature of processing of the initial component (grinding, extrusion etc.). Barrel temperature, rotational speed and torque are some of the input variables during the filament processing which largely affects the mechanical sustainability of the FDM fabricated parts (Singh *et al.*, 2017a,b,c, 2018d; Singh and Kumar, 2017). FDM as 3D printing technique is most economical way of producing 4D thermoplastic composite reinforced with nano-particle using extrusion process for the development of customized material for maintenance of heritages structures.

Proposed Concept for Maintenance of Heritage Structures

The present way of maintenance is based upon traditional practices, which consume lot of time especially when some artistic work is involved. This makes the project cost high and leads to more down time. Some researchers have proposed the use of 3D scanners and 3D printing of mortar etc. for fast maintenance, but hitherto no work has been reported for use of debris of heritage structure itself (for more compatibility) with reinforcement of plastic solid waste through cryogenic grinding followed by extrusion and preparation of feed stock filament for 3D printers. This will significantly improve the processing ability of debris as well as waste management of plastic solid waste. The repaired/modified structures needs to be checked for thermal stability, dynamic mechanical analysis and aesthetic effects. 3D scanning is an important measure of dimensional parameters. A portable 3D scanner can fulfill the requirement of checking exact dimension of damaged parts of heritages. 3D scanner installed with design software then process 3D images into part of damaged filler so that prototypes on 3D printer can be fabricated. The design parts by help of 3D scanner now processed by slicing software to ensure the infill density, printing speed, printing temperature, layer thickness and infill pattern of the part to be prepared on 3D printer. The next step of the proposed methodology is to collect the debris of identified sites, which will be segregated by sieve shaker and then processed with cryogenic milling at -96°C to ensure the enhanced mixing capability with polymeric matrix. In next stage, blend of debris and thermoplastic processed on cryogenic milling is analyzed on melt flow indexing setup and DSC to ensure the flowability and thermal stability of the mixtures. If the thermal stability and melt flow index of matrix are under the acceptable limit then those mixture are processed on the twin screw extruder setup for preparations of feedstock filaments. The feedstock filament of suitable diameter (usually 1.75 mm in commercial FDM setup) will be used as the input material. By following the step discussed above, the customized material for maintenance of heritage structure can be prepared. It should be noted that ultimate characteristic of the feedstock filament will be a result of input process variable applied for processing of material. The next step involved in the present study starts with 3D printing of customized geometry scanned through 3D scanner. Here it should also optimize the input process variable so that fabricated part must attain the uniform material properties. Now the printed part as functional prototype is tested by dynamic mechanical analysis (DMA) setup for ascertaining the storage and loss modulus, SEM, XRD analysis (for ensuring uniform dispersion) and bonding capabilities through FTIR. The destructive testing like; pull out test, impact loading test and tensile test may be performed on the final prototypes to ensure the load bearing capabilities.

The 3D printed parts on FDM can be applied directly on the damaged site in the two different ways. First is use of cement-based adhesive for masonry/construction work and second is use of agricultural waste material for similar work depending upon the age/year of establishment of particular structures. For cement-based masonry/construction sites the debris availability is quite simple and same can be easily blended with polymeric waste after cryogenic treatment and final prototypes (replicas) can be prepared by extrusion and FDM processing. After preparation of replica, the same will be exposed to some chemical environment (like acetone for ABS matrix material) in vapour smoothing station. This will expose the cement powder particles on the outer surface and will provide finished surface up to nano level. The exposed cement particles can have a bonding with other end of the damaged structure with little quantity of water as per regular practices in construction sites. Finally, no post finishing is required as nano level finished structures are available. In the second case for debris other than cement, the same has to be blended with polymeric waste for development of feed stock filament. Here the advantage is that suppose one need 100 g/mm^3 of filler for maintenance of some cavity in the structure and debris available is 10 g/mm^3 . The rest can be filled by thermoplastic which is blended in available debris to make it as 100 g/mm^3 . The finally prepared replica will be pasted on site after post finishing and hence very less time on site will be consumed.

In case of load bearing structures with cyclic loading cases the replicas prepared will be checked for dynamic mechanical analysis so that their storage modulus and loss modulus is computed. As the ratio of storage modulus to loss modulus reflects the ability to absorb shocks under cyclic loading, in case the existing structure stability is questionable the same can be reinforced to improve its storage modulus by increasing the proportion of plastic solid waste. Before applying the plastic solid waste in heritage structure their melt flow characteristics and thermal graphs using differential scanning calorimetry (DSC) will be used to ensure thermal stability under different temperature conditions.

Working Mechanism of Proposed Framework

As per Maxwell's right-hand thumb rule, assume current carrying wire in right hand and thumb's direction denotes the direction of the current flow then direction in which hand is wrapped, represents the direction of magnetic lines of forces. If we take two different parallel current carrying conductors, then two cases emerges: the first case can be emerged as current flow of both conductors is in same direction and second case can be the current flow of both conductors in opposite directions. If the current of two current carrying conductors flows in a same direction then magnetic lines of forces will attract to each other and there will be contraction. Similarly, if the current flows in opposite direction then magnetic lines of forces will repel each other and there will an expansion (which can be noted as the physical quantity).

In the present work, a novel technique for recycling of plastic/polymer waste has been proposed for four dimensional printing applications especially for heritage structures. The idea is to use multi-jet extrusion nozzles of fused deposition modelling setup for printing multi layers of conducting thermoplastic composite (like: graphene reinforced thermoplastics) and non-conducting polymer waste (like ABS, Nylon6). The framework of 4D printing is shown in Fig. 1.

Fig. 1 Framework of 4D printing.

Fig. 2 Methodology for maintenance of heritage structures.

Now if current is passed in same direction between two parallel conductors than by basic principle two conducting wires will generate magnetic field and will attract each other. Similarly when the direction of current between two parallel conductors is reversed they will experience repulsive force. This basic principle has been used to develop new/in-house, 4D printing materials. With this multi material sandwiched component, just by changing the direction of current flow the component will change its thickness, because of change in magnetic field. Finally this helps to fill the cavities emerged in heritage structure (which may be of irregular contour). It should be noted that the flow of current in opposite direction will leads to expansion (as per the space available in the cavity) and one needs to supply the current (quantity) and control the time for flow of current in such a way that it leads to permanent fatigue of thermoplastic material. This will help in self assembly of the polymeric composite into the cavity. As the functional prototypes are prepared off line in some lab environment the down time in maintenance at the heritage site is significantly reduced resulting in cost benefits and waste management of thermoplastics.

Methodology of Proposed Concept

Fig. 2 shows detailed methodology for the development of customized material for maintenance of heritage structures.

Damages in the heritage structures can be of different shapes and size like; flat cylindrical, flat rectangular, conical shapes, trapezoidal, flat triangular etc. **Fig. 3** shows occurrence of common damages in the heritages structures. If the damages geometries are of type 3(a) and 3(b) then the additively manufactured prototypes (of customized material) can act as the filler material for maintenance. But if the damaged section is found to be of **Fig. 3(c)** type (regular/irregular trapezoidal with small inlet) then the problem of material filling might be difficult and it is needed to make an enlargement of that damaged hole to be repaired but enlarging of hole will lead to reduce the strength of that structures.

If the damage of structures is found to be of **Fig. 3(c)** type then the multi-material printing by use of FDM may be one of the best solutions for maintenance. Infield practice, 3D printing of alternating layers of conducting and non-conducting layer of piezoelectric material may be used as filler material on the damaged cavities. Suppose the multi-material printed prototype/replica of cavity consisting of alternative conducting and non-conducting layers are fitted into the cavities as shown in **Fig. 3**, the flow of current in the opposite direction of each layers will repel each layer leading to an expansion of the filler material, resulting into the self assembly.

Fig. 3 Common structural damages in heritage structures.

Fig. 4 3D printed polymeric waste component.

Table 1 Mechanical properties of 3D printed multi-material component

Material	Peak load (N)	Peak strength (MPa)	Peak elongation (mm)	Percentage elongation at peak (%)	Young's modulus (MPa)	Yield stress (MPa)
HAP	161.3	8.40	3.04	4	325.00	1.00
AHP	133.9	6.97	2.85	4	72.92	2.73

Polymer Waste Material 3D Printing: A Case Study

Multi-material 3D printing is precursor of present framework which can lead to the preparation of composite structures for maintenance of heritage structures. The alternating layer of conducting and non-conducting layers can be printed easily. In this study, commercial open source FDM setup (Company: Divide by Zero) configured with two nozzle head was selected for multi-material 3D printing. The static parameters for fabrication of composite parts were nozzle diameter of 0.3 mm, filament diameter of 1.75 ± 0.05 mm, layer height 0.27 mm, 3 perimeters (by adjusting 3 top and 3 bottom layers), rectilinear fill pattern, 30 mm/s perimeter speed, travel speed of 130 mm/s, at extrusion temperature of 250°C , bed temperature of 55°C , infill percentage of 100%, and under printing speed of 50 mm/s. The multi-material printing was customized by total 12 layers with 04 layers of each material. The multi-material printing was configured as:

- (1) 04 layers of recycled HIPS on bottom, 04 layers of recycled ABS in middle and 04 layers of recycled PLA on top (HAP),
- (2) 04 layers of recycled ABS on bottom, 04 layers of recycled HIPS in middle and 04 layers of recycled PLA on top (AHP) and
- (3) 04 layers of recycled PLA on bottom, 04 layers of recycled ABS in middle and 04 layers of recycled HIPS on top (PAH).

So, 03 different pieces of varying material as HAP, AHP, PAH have been printed on FDM setup as shown in Fig. 4. It should be noted that HIPS, ABS and PLA selected for printing are primary recycled (commercially available in open market) and can be treated as waste thermoplastics. Here no reinforcement of debris has been made, but by maintaining the debris proportion in thermoplastic matrix based upon rheological properties as per ASTM D1238 for melt flow index and thermal stability, glass transition temperature (analysis based upon DSC) one can easily prepare the feed stock filament for FDM and 3D printing of functional prototypes can be performed.

Fig. 5 Micrographs of additively manufactured multi-material components, (a) HAP, (b) AHP, (c) PAH.

It has been observed that 3D printed HAP resulted in the maximum values of peak load, peak strength, peak elongation, percentage peak elongation, Young's modulus and Yield stress (See [Table 1](#)).

[Fig. 5](#) shows micrographs of HAP, AHP and PAH parts (at30X) prepared on FDM (as per [Table 1](#)). Here, it should be noted that mechanical properties of HAP based component has resulted into the maximum tensile strength. This may be because layers of HAP overlapped uniformly to produce stronger joints. Whereas AHP and PAH were observed weaker because their layers are not tightly stacked. Now by selecting materials with alternative conducting and non conducting layers, expansion and contraction of the filler material can be easily controlled for self assembly in the cavity.

Summary

In this article, a frame work for maintenance of heritage structure through AM route has been proposed. The proposed route for development of customized materials for maintenance of damaged structure leads to some interesting features like:

- Reduction in time and cost of maintenance can be achieved by the proposed method for development of customized material for maintenance of heritages structures, as it leads to concept of self assembly.
- The proposed route is the one of the novel way to manage plastic waste into useful constructive prototypes, especially in 4D applications. Any intricate cavity shape can be easily self-assembled with proposed methodology.
- Inhouse developed polymeric material blend with reinforcement of debris recovered from heritage site can be useful for development of maintenance material at low cost.

Acknowledgement

The authors are highly thankful to manufacturing research lab (GNDEC, Ludhiana) for providing financial/technical assistance to carry out the research work.

Statistical Analysis of Energy Absorption in Aluminum Foam Sandwich Under Impact Testing Using the Taguchi Design

Muataz HF Al Hazza, Amalina Endut, Erry YT Adesta, Nur AB Ibrahim, and Mohammad Y Ali, International Islamic University Malaysia, Kuala Lumpur, Malaysia

Introduction

Demand for the use of porous materials in industries is increasing due to the need to reduce the weight of structural parts in most of industries in order to improve market competitiveness. One of the alternatives that have been developed recently was metal foam. Metal foam consist of two types of cell topology which is open-cell and closed-cell foam. The requirement of producing complex parts with advanced material properties and lighter weight are generally needed nowadays especially in structural parts in aerospace, automotive and marine industries. However, foam itself is weak and can not be used alone. therefore, to overcome the problem, researchers had generated a new technology of lightweight material which is Aluminum foam sandwich (AFS). In AFS the metal foam used as a sandwich's core with two sheets as a skin to have interesting properties such as good stiffness and strength to weight ratio, good sound damping, excellent energy absorption and thermal insulation (Styles *et al.*, 2007; Crupi and Montanini, 2007). One of the most encouraging advantages in AFS is the high energy absorption properties. Therefore, the need to understand and investigate the ability of these materials in different applications becomes one of the most important issues. Many researchers investigated the mechanical behavior of the AFS. However, few of them were focused on analyzing the relationship between the skin and core thickness with the ability of energy absorption.

Crupi and Montanini (2007) mentioned that the Aluminum foam sandwich has a lightweight structure with good dissipation of energy under impact and high mechanical strength. By reducing the weight of structural parts, energy consumption can reduce which in turn leading to lessen oil consumption. One of the excellent metal foam that are used by previous researchers in automotive application is Aluminum foam sandwich due to their unique properties such as low density, good energy absorption characteristics. According to Ruan *et al.* (2010), stated that Aluminum foam sandwich panels are good energy absorbers and lightweight which provide wide range of potential applications in automotive industries. Example of the testing methods are compression test, impact test and quasi-static indentation test. All of the testing methods are done by following the standard of ASTM. Shunmugasamy and Mansoor (2018) stated that AFS have been used as energy absorbers, acoustic dampers and weight saving members in automotive and aerospace structures.

Fotsing *et al.* (2016) evaluated the mechanical behavior for composite sandwich structures by performing tensile tests, compressive tests, impact tests and three-point bending tests. The composite sandwich structures are made of honeycomb core and woven carbon epoxy face sheets. All of these tests offer good information about the vibration damping of composite sandwich structures. Srivastava (2012) investigated the impact behavior of composite sandwich structure in order to analyse the energy absorbed and fracture toughness. Izod impact, charpy impact and weight drop test had been performed on the sandwich structures. Glass fiber-reinforced and polyurethane foam were used to prepare the composite sandwich structure.

Damghani and Gonabadi (2017) conducted drop hammer test to investigate the perforation responses of Aluminum foam sandwich by varying the velocities, relative density of Aluminum foams and weights of projectile. The samples were impacted at different energy levels to attain various damage mode levels. Based on the findings, it revealed that by increasing the relative density of Aluminum foam and velocity, the energy absorption of sandwich structure increases.

Meanwhile, Mohammed *et al.* (2014) conducted the low velocity impact test by analyzing the mechanical response of sandwich composites. The most striking result to emerge from this study is that the mechanical behavior of sandwich structure is strongly reliant on the loading rate.

Additionally, Tsuchikura *et al.* (2013) conducted charpy impact test on sandwich composites. Carbon fiber reinforced polymer and acrylonitrile butadiene styrene (ABS) have been used as a core and face sheets for sandwich composite construction. Evaluation of charpy impact test velocity and impact fracture energy had been discussed in this study. The concluded that the new method allows for more efficient beam contact to the inner core and its surface permitting deeper areas in thick laminated composites

Furthermore, Hufenbach *et al.* (2008) performed low-velocity impact which was charpy test on composite structures to observe the impact damage tolerance. Specifically, this study aims to evaluate the factors that give influence to the impact response of composites which are fiber strengths, toughness, thickness of panel, impact velocity and support conditions. The study showed good correlation between experimental and numerical results. Arifin *et al.* (2014) studied the impact behavior of the polymer matrix composites by varying design of the lamination structure. The findings highlighted that selection of reinforcement and matrix types play vital factor for ability to absorb more energy during impact test.

Most of researchers were focusing on determine behavior of closed-cell foam while least of them discuss on open-cell foam. None of them if any have investigate skin to core ratio effect on mechanical behavior of open-cell Aluminum foam sandwich and analyse statically the relationship between the skin and core thickness with the energy absorption ability. Therefore, this present study examines the energy absorption of Aluminum foam sandwich (AFS) with open-cell foam core using Impact testing.

Material Preparation

Aluminum foam sandwich are produced using the following steps:

- Aluminum sheet with thickness of 0.4 mm, 0.6 mm, 0.8 mm as shown in Fig. 1(a),
- Aluminum foam with thickness of 3.2 mm, 5.6 mm and 6.35 mm as shown in Fig. 1(b) and,
- Epoxy resin and hardener as shown in Fig. 1(c).

The Aluminum foam was attached together with Aluminum sheets using the epoxy resin with hardener ratio of 2:1 to fabricate Aluminum foam sandwich as shown in Fig. 2.

As in the ASTM standard of C393, the preferable ratio of skin to core ratio is approximately less or equal to 0.10 in order to select the suitable thickness for core and skin which has been followed in this investigation.

Table 1 Design of experiment

Parameters	L1	L2	L3
Skin thickness, mm	0.6	0.8	1.0
Core thickness, mm	3.2	5.6	6.35

Charpy Impact Test

Charpy impact test were conducted on AFS samples in order to analyse the energy absorbed in breaking the sample that subjected to shock loading according to ASTM standard D4812. During the test, the pendulum is elevated to certain height and allowed to fall while impact velocity is maintained at 3.35 m/s. When the pendulum strikes, it impacts and breaks the sandwich specimens (Srivastava, 2012). Fig. 3 shows the Charpy impact test machine. The specimens for conducting the impact test are shown in Fig. 4. The designation was in rectangular shape with the value of width, 3 mm and length, 64 mm based on ASTM D4812 standard.

Design of Experiment (DOE)

Taguchi design for two independent parameters of core and skin thickness, with three levels has been developed. L^9 orthogonal array have been generated using JMP statistical software (version 11). Levels and main parameters are shown in Table 1. Nine runs of Charpy impact test have been conducted and repeated for three times.

Finally, all of the experimental results are evaluated using Taguchi method by generating the levels and combination input of parameters. Meanwhile, the optimization of the selected parameters is generated using desirability function analysis in order to obtain the maximum responses such as peak force, energy absorbed and impact energy of Aluminum foam sandwich.

Charpy impact test had been conducted with various thickness of Aluminum foam and Aluminum sheet in order to determine the impact behavior of Aluminum foam sandwich. The Charpy impact test was conducted three times for each condition. Nine runs of the test have been performed by varying the thickness of Aluminum foam as core and Aluminum sheet as a skin. Fig. 5 demonstrated the summary of the Charpy impact test for different thickness of Aluminum foam and Aluminum sheet for the three different Runs.

It can be clearly seen that by increasing skin and core thickness, the impact energy of Aluminum foam sandwich increased as well. This current finding is consistent with the previous studies by Ozdemir *et al.* (2015) in which they found that increasing the core and skin thickness eventually increase the impact energy of the sandwich structure. It is apparent from the results that the highest impact energy was 21.67 J for skin thickness of 1.0 mm and core thickness of 6.35 mm.

The current result was in line with the finding of Hufenbach *et al.* (2008) that found by increasing the skin and core thickness, the impact energy of AFS sample increased eventually. Hence, the selected parameters which were skin and core thickness give improvement in terms of good energy absorption by conducting the impact test.

However, the types of failure modes for all tested AFS samples under impact testing are presented in Table 2 by varying the core and skin thickness as selected parameters.

Table 2 shows two main types of failure modes that occurred when AFS sample subjected to impact loading namely skin-core delamination and rupture image is shown in Fig. 6.

The failure mode can result in rupture with different of thickness of core and skin. This may due to different configurations of sandwich structure. The delamination occurs between skin and core layer. This failure was mainly affected by collapse of core cells due to buckling of core itself. The rupture behavior when subjected to impact loading, the core and skin were not fully separated due

Fig. 5 Summary of Charpy impact test for different thickness of core and skin.

Table 2 Failure modes for each of the AFS samples under impact test

Run	Parameters		Failure modes
	Skin thickness, mm	Core thickness, mm	
1	0.6	3.2	Delamination
2	0.8	3.2	Delamination
3	1.0	3.2	Rupture
4	0.6	5.6	Rupture
5	0.8	5.6	Delamination
6	1.0	5.6	Delamination
7	0.6	6.35	Rupture
8	0.8	6.35	Delamination
9	1.0	6.35	Delamination

to the flexibility of unbroken structure of sandwich itself. The findings of the current study were in line with [Hufenbach et al. \(2008\)](#) which found that rupture mode form the limited damage sizes in skin and core.

Statistical Analysis

The statistical analysis was covered the: summary of fit; analysis of variance (ANOVA); surface profiler and profiler. [Table 3](#) concluded the summary of fit measures.

[Table 3](#) shows high value of R^2 and R^2 adjusted. Moreover they are very close to each other together which mean that the process is almost free from the insignificant terms.

Analysis of variance (ANOVA) has been calculated and concluded in [Table 4](#). The ANOVA and F ratio test was calculated to justify the goodness of fit of model.

Fig. 6 Failure modes of AFS.

Table 3 The summary of fit

R Square	0.944584
R Square adjusted	0.911334
Root mean square error	1.655643
Mean of response	15.07778
Observations (or Sum Wgts)	9

Table 4 Analysis of Variance (ANOVA)

Source	DF	Sum of squares	Mean square	F Ratio
Model	3	233.61867	77.8729	28.4088
Error	5	13.70578	2.7412	Prob > F
C. Total	8	247.32444		0.0014*

Fig. 7 Actual Data and predicted data.

From **Table 4** it is clearly show that results and the parameters selection with high correlation to the investigated response with the F ratio of 0.0014 which is the ratio of two mean square values and it is less than 5% and means that the level of significant. Finally, to have more understanding for the whole process the relationship between the actual data and the predicted data was extracted and plotted as in **Fig. 7**.

The leverage plots which consists of skin thickness, core thickness and skin thickness*core thickness were developed as shown in **Fig. 8**. The leverage plots showed the unique effect of a term in the model.

Fig. 8 Leverage plots.

From **Fig. 8**, it can be concluded that the core thickness is the most significant term in the model with the p value of 0.0003.

Conclusion

The following conclusions can be drawn from the present study:

The results showed that the selected parameters have high correlation with the responses of the results with the F ratio of 0.0014 and it is less than 5% hence, the level is significant. However, the core thickness is the most significant term in the model with the p value of 0.0003. Both skin and core thickness have a significant effects when impact on energy absorption. The statistical analysis revealed that the core thickness is more related to energy absorption.

There are two main types of failure mode observed in this investigation when AFS sample subjected to impact loading with skin-core delamination and rupture. Both skin thickness and core thickness have a positive effect on energy absorption in AFS.

Introduction

Plastics are manufactured from non-degradable polymers such as polystyrene, polyethylene and many more, in which their light weight and long-lasting property are causing terrible environmental pollution. To overcome the problem, researchers are exploring on biodegradable materials that can substitute conventional polymers. Among the biodegradable polymers, polylactic acid (PLA) is a biodegradable aliphatic polyester derived from lactic acid, which can be obtained from the fermentation of starchy materials (Mehta *et al.*, 2006). In spite of many attractive properties of PLA, such as biodegradability, high strength and modulus, PLA shows lower flexibility and higher cost, thus limiting the applications of PLA (Rasal *et al.*, 2010).

Epoxidized soybean oil (ESO) is an epoxidized derivative of a mixture of esters of glycerol with various saturated and unsaturated fatty acids. In previous study, ESO has been used as a plasticizer in PLA with 38% increase in elongation at break with 20 parts per hundred (phr) ESO loading (Ali *et al.*, 2009). However, the tensile strength, yield stress and modulus of PLA decreased with addition of plasticizer. It has been reported that addition of plasticizer generally increases the elongation at break but decreases the strength and modulus. Thus, one method that can be used to improve the properties of polymer matrix is by incorporating fillers such as clay (Pluta *et al.*, 2006a; Najafi *et al.*, 2013). Incorporation of clay into PLA exhibited improvement in water vapor barrier and antimicrobial properties (Rhim *et al.*, 2009; Castro-Aguirre *et al.*, 2018).

There are two methods that can be used to disperse the clay in polymer matrices: solution blend and melt blend. In the solution blend method, solvent is used in large amount to dissolve the polymers thus, improving the intercalation of polymer chains and clay platelets (Ozdemir *et al.*, 2016). Whereas, for melt blend method, the layered silicate is mixed with the polymer matrix at the melting temperature of the polymer. This method is mostly used as it is more environmental friendly and polymers can be melt processed. It has been reported that the PLA/clay nanocomposites were prepared by melt blending of PLA with sepiolite and halloysite clays (Russo *et al.*, 2014).

The addition of oligo(ϵ -caprolactone) as compatibilizer has improved the dispersion of silicate layers in nanocomposites (Ray *et al.*, 2002). Enhancement of properties such as crystallization rate (Pluta *et al.*, 2006b), tensile, impact strength, modulus (Najafi *et al.*, 2015), gas permeability, water barrier property (Şengül *et al.*, 2017) and biodegradability (Castro-Aguirre *et al.*, 2018) were observed in PLA/clay nanocomposites. Dispersion of clay is very crucial in obtaining homogeneously dispersed filler in polymer matrix, in which, dispersion of clay in PLA matrix using electric effect was reported by Geun *et al.* (2016).

Thus, this study aimed to prepare PLA blend using ESO as a plasticizer and Cloisite 30B as an organoclay. The PLA/ESO/organoclay nanocomposites were melt mixed with different ratios of organoclay and then investigated the structural, thermal, mechanical and rheological properties of the nanocomposites.

Experimental

Materials

Polylactic was obtained from Cargill-Dow molecular weight (M_w) of 148,000 g/mol, and polydispersity index (PDI) of 1.9, epoxidized soybean oil (ESO) with epoxide content of 6.9 wt% was obtained from Shindongbang Co, Korea. Organoclay, Cloisite 30B was received from Southern Clay Products Inc.

Preparation of PLA/ESO/Organoclay Nanocomposites

PLA, ESO and Cloisite 30B were dried overnight at 40°C in vacuum. The PLA was melt-blended with 20 parts per hundred (phr) of ESO in a Haake internal mixer at 180°C with a rotor speed of 60 rpm for 10 min. And then Cloisite 30B was added into the internal mixer as ratio mentioned in Table 1 and mixed for another 10 min. The nanocomposites were then molded into 1 mm thickness sheet under a pressure of 44.482 kilonewton (kN) at 180°C for 10 min.

Characterizations

The X-ray diffraction (XRD) patterns were recorded on a Philips, X'pert PRO MRD diffractometer using a CuK α radiation ($\lambda = 1.54 \text{ \AA}$) at voltage of 40 kV and current of 25 mA. The XRD was used to evaluate the dispersibility of the organoclay silicate layers in the PLA matrix. Morphology of the nanocomposites was obtained by transmission electron microscope using LEO-912AB with omega energy filter at

Table 1 Formulation and sample code of PLA/ESO/organoclay nanocomposites (PLAESOCNs)

Sample code	PLA/ESO/Cloisite 30B (phr)
PLAESO	100/20/0
PLAESOCN-1	100/20/1
PLAESOCN-3	100/20/3
PLAESOCN-5	100/20/5
PLAESOCN-7	100/20/7

**Fig. 1** XRD patterns of Cloisite 30B (C30B) and PLA/ESO/Cloisite 30B nanocomposites (PLAESOCNs).

120 kV accelerating voltage. The samples for TEM analysis were all microtomed before the test. TEM was used to observe the dispersion of the organoclay silicate layers in the PLA matrix. Differential scanning calorimetry (DSC) was performed using DSC2010 from TA Instruments. The DSC scans of the samples were run from 0°C to 200°C at the rate of 10°C/min and then kept at 200°C for 5 min to eliminate the previous heat history and subsequently cooled to 0°C at the rate of 10°C/min. The samples were heated again to 200°C at 10°C/min. This second heating process was regarded as melting scan for the analysis. The glass transition temperature (T_g), cold crystallization temperature (T_{cc}), cold crystallization enthalpy (ΔH_{cc}), melting temperature (T_m) and melting enthalpy (ΔH_m) were determined. Temperature at the maximum values were determined as crystallization and melting peaks. Tensile properties were measured using universal testing machine (United Co. STM 10E) at 25°C and with a crosshead speed of 5 mm/min according to ASTM D412 specifications. The tensile test was used to determine the elongation at break, modulus and yield stress. Melt rheological analysis (small amplitude oscillatory shear rheometry) was carried out in a RMS 800 instrument. The dynamic oscillatory shear measurements were conducted at 180°C using a set of 25 mm diameter parallel plates and a sample of 1–2 mm thickness. Preliminary strain sweep test was carried out at frequency of 100 rad/s at 180°C to estimate the linear viscoelastic range of the samples. Afterwards, frequency sweep tests in the linear viscoelastic regime were conducted between 0.1 and 100 rad/s.

Results and Discussion

Structural Properties of the Nanocomposites

The XRD patterns of the Cloisite 30B and PLAESOCN nanocomposites are shown in Fig. 1. The peak corresponding to the basal spacing of the organoclay (C30B) appears at 4.74° (d_{001} spacing is 1.9 nm). As can be observed in Fig. 1, diffraction peaks were not observed in PLA/ESO/organoclay nanocomposites (PLAESOCNs). This implies that silicate layers of organoclay were exfoliated in the PLAESO blend matrix. One possible explanation is that the ESO penetrated into the clay layers and expanding the basal spacing of the layers. This leads

to exfoliation of silicate layers in the nanocomposites. Similar effect of plasticizer was also reported in PLA/clay nanocomposites where exfoliation was dominant compared to non-plasticized PLA/clay nanocomposites (Guralp and Sebnem, 2009).

Dispersion of the clay layers in the polymer matrices of PLAESOCN-5 was confirmed by TEM as illustrated in Fig. 2. Exfoliated (label "C") silicate layers were observed in PLAESOCN-5. The XRD patterns and TEM images confirmed on the delamination of silicate layers in the PLA/ESO/organoclay nanocomposites.

Thermal Properties

The DSC thermograms obtained from second heating scan of PLA/ESO/clay nanocomposites (PLAESOCNs) is shown in Fig. 3. The transition temperatures and enthalpies determined from the thermograms are summarized in Table 2. The glass transition temperature (T_g) of PLAESOCNs increased with the increased of clay content. It increased from 53.7°C for PLAESO to 55.8°C for PLAESOCN-5. The T_{cc} of the PLAESOCNs were also increased with organoclay content. This indicates that organoclay restricts the mobility of polymer chains.

PLAESOCN-5	55.1	106.4	25.7	154.6	3.5	163.5	22.9	26.4
PLAESOCN-7	55.8	107.1	27.4	154.8	3.5	164.3	24.4	27.9

**Fig. 4** Stress-strain curves of plasticized PLA (PLAESO) and PLA/ESO/Cloisite 30B nanocomposites (PLAESOCNs).

Mechanical Properties

The stress-strain curves for PLAESOCNs is shown in Fig. 4. It was observed that elongation at break of PLAESOCNs decreased with addition of organoclay content into PLAESO blend. Similar observation was also found in the incorporation of clay in PLA/PEG/clay nanocomposites causing decreased in elongation at break (Shibata *et al.*, 2006). Fig. 5 shows the Young's modulus and yield stress of PLAESO and PLAESOCNs. There were significant increases of modulus for PLAESOCNs as compared to PLAESO blend. This is expected when higher aspect ratio and larger surface area of silicate layers organoclays are incorporated into polymer matrix. The yield stress of PLAESOCNs was increased with organoclay content as compared to PLAESO blend. The mechanical analysis showed that the organoclays improved the stiffness and yield stress of the PLA/ESO blend.

Rheological Properties

Preliminary strain sweep tests were performed to estimate the linear viscoelastic range of the PLAESO blend and PLAESOCN-5 nanocomposite. As shown in Fig. 6, the strain sweep measurements were carried out at frequency of 100 rad/s on the PLAESO and PLAESOCN-5 sample. The linear viscoelastic limits extend to a strain of 50% and 6.1% for PLAESO and PLAESOCN-5, respectively. Therefore, the linear viscoelastic properties of PLAESO and PLAESOCNs were conducted at a strain of 5%.

Fig. 5 Young's modulus and yield stress of plasticized PLA (PLAESO) and PLA/ESO/Cloisite 30B nanocomposites (PLAESOCNs).

Fig. 6 Storage modulus (melt state) of PLAESO and PLAESOCN-5 as a function of strain amplitude.

As shown in **Fig. 7**, the storage moduli (G'), loss moduli (G'') and complex viscosities (η^*) of PLAESOCNs were higher than those of PLAESO at all frequencies and increase monotonically with the clay content, especially at low frequency (< 10 rad/s). Both moduli of PLAESOCNs showed weak frequency dependence and gradual changes of behavior from liquid-like to solid-like with increasing organoclay content in the PLAESO matrix. The terminal zone slope of PLAESO and PLAESOCNs is shown in **Table 3**. The slope of $G'(\omega)$ and $G''(\omega)$ in the terminal region of the curves of PLAESO matrix is 1.2 and 0.97, respectively, and these values are in range expected for polydisperse polymers (Pluta *et al.*, 2002). On the other hand, the slopes of $G'(\omega)$

Fig. 7 (a) Storage modulus, (b) Loss modulus and (c) Complex viscosity of PLAESO and PLAESOCNs as a function of frequency.

Table 3 Terminal region slopes of $G'(\omega)$ and $G''(\omega)$ for PLAESO and PLAESOCNs

Samples	slope of $G'(\omega)$	slope of $G''(\omega)$
PLAESO	1.2	0.97
PLAESOCN-1	1.0	0.95
PLAESOCN-3	0.8	0.85
PLAESOCN-5	0.23	0.50

and $G''(\omega)$ were considerably lower for all PLAESOCNs. The differences in slopes may be attributed to difference in extent of exfoliation. A larger extent of exfoliation will lead to more solid-like behavior due to the increased number of particle-polymer interactions.

Conclusion

The PLA/ESO/organoclay nanocomposites were prepared using melt mixing method. XRD patterns showed that silicate clay layers were exfoliated in the nanocomposites and confirmed by TEM. Thermal properties exhibited slight increase in glass transition temperature and cold crystallization temperature of PLA. The mechanical analysis revealed that the organoclays improved the

stiffness and yield stress of the nanocomposites. Rheological studies under dynamic frequency sweep showed that storage modulus at low frequency region of the nanocomposites exhibited solid-like behavior with higher organoclay content. This study showed the enhancement in properties of PLA/ESO/organoclay nanocomposites and its processability in presence of organoclay with different ratios.

Introduction

The construction industry is responsible for large consumption rates of natural resources, with demand levels reaching up to 40% of the total materials consumed worldwide (DPTI, 2017). In addition, the construction industry generates large amounts of waste, accounting for 33% of all waste generated in the European Union (European Environment Agency, 2010). The concept of sustainability in construction has always been linked to the quest to reduce impacts of construction operations, particularly environmental ones (Rosen, 2012). Industry professionals and researchers around the world have been attempting to study alternative technologies, materials, and design concepts that are less damaging to the environment, and that can be readily adopted on construction projects.

When considering the minimization of environmental impacts, it is imperative that this is related to the entire life cycle of the project, from the extraction and processing phase of raw materials, to the final disposal of the elements (Akadiri *et al.*, 2012). In this context, different methods of analysis were developed, including the spontaneous or 'Ad Hoc' method (Stamm, 2003) and interaction matrix method (Finucci, 2010). However, one of the most widespread concepts around the world today is the life cycle assessment (LCA) approach, being used in several fields, including the construction sector.

According to United Nations Environment Programme (UNEP), *Life Cycle Thinking* is a way of providing information to stakeholders so that they can make the best decisions regarding the life cycle of products and services, and their impacts based on the triple bottom line of sustainability: social, environmental and economic factors (UNEP, 2013). As stated in the general principles of sustainability in building construction described in ISO 15392, all these three dimensions are necessary in a sustainable assessment (ISO, 2008). However, it is possible to restrict the assessment to an individual dimension, depending on the scope considered in the analysis.

When it comes to environmental studies conducted in the construction industry, difficulties arise due to the high degree of detail required when considering an entire building as a functional unit of analysis. For example, it is important to consider that buildings have a comparatively long life and they often have multiple functions, in addition to the fact that they contain many different components and are normally unique (Bribián *et al.*, 2009). As a result, this research explores the use of LCA in the construction sector, presenting the limitations still existing and elaborating a proposal of how the studies on this theme should be carried out in the future.

This paper is organized as follows: in the next section, the significance of the use of LCA on building projects is highlighted. The section that follows then presents a more detailed explanation of the LCA methodology. Based on the presented methodology, the main challenges of applying LCA to building construction projects are raised. Final concluding remarks are then discussed to outline the path expected to be followed in the future to enhance the sustainability of the construction projects.

LCA Methodology

Significance of LCA in Construction

Several methodologies and initiatives have already been created in the construction sector with the aim of sustainably evaluating buildings and acquiring associated sustainability rating systems and certifications. This includes BREEAM - BRE Environmental Assessment Method (Baldwin, 1998), LEED - Leadership in Energy and Environmental Design (Clevenger, 2008), NABERS - National Australian Building Environment Rating Scheme (Seo *et al.*, 2005), among other examples. Many of the existing certification schemes, however, do not analyze the environmental impacts at each stage of the building's life cycle. That is why the LCA approach has been prominent in research and in the marketplace as a means for combating such shortcomings. LCA is a technique for assessing and quantifying possible environmental impacts throughout the life cycle of a product or process (ISO, 2006a). When applied to a building project, LCA evaluates the building performance and analyzes the potential impacts generated throughout the building's life cycle, along with quantifying materials and construction processes, and their environmental repercussions (de Larriva *et al.*, 2014).

Environmental assessments are often used to assess the impacts associated with manufacturing and maintaining a particular service, product, or system (Karl *et al.*, 2019). But when considering the long lifespan of a building, it is not enough to choose materials and processes that generate few impacts during the manufacturing stage. It is necessary to evaluate the complete life cycle of the building until its demolition (Najjar *et al.*, 2017).

LCA allows the analysis of the environmental impacts permeating all these stages of the building life cycle. In addition, this methodology is already widely disseminated, with several technical standards, computer programs and databases capable of assisting professionals in this work (Anand and Amor, 2017). Using this approach, engineers, architects, and builders can make less environmentally damaging decisions in their construction projects. An overview of LCA is given next.

Overview

The International Standards Organization (ISO) published the most recognized standards of LCA methodology (Khasreen *et al.*, 2009), including ISO 14040 Principles and framework and ISO 14044 Requirements and guidelines.

According to ISO 14040, LCA is the compilation of inputs, outputs and potential environmental impacts of a product system throughout its life cycle (ISO, 2006a). The information generated can be used to improve processes, support public policies and can serve as a basis for decision making. When applying LCA from a building's perspective, the methodology aims to assess the environmental impacts resulting from building materials and building techniques adopted at different stages of the project's life cycle (Figueiredo, 2018).

The most common LCA method is referred to as a 'cradle-to-grave' approach since it encompasses the stages of extraction of raw materials, up to the final disposal of the building components after demolition, where all materials return to nature. LCA also permits demarcating the boundaries of the study in other partial ways, including cradle to gate, gate to gate and gate to grave (ISO, 2006a).

Overall, LCA consists of four main steps: (i) goal and scope definition; (ii) Life Cycle Inventory (LCI) analysis; (iii) Life Cycle Impact Assessment (LCIA); and (iv) Interpretation (ISO, 2006a). These phases are represented in Fig. 1. The first step is intended to guide the subsequent work. Some other definitions need to be specified at this stage: the *Functional Unit*, describes the primary function fulfilled by a product system, and indicates how much of this function is to be considered in the intended LCA study (Guinée, 2002); the *System Boundary*, refers to how far the analysis will be done; the *assumptions and limitations* need to be specified; and finally, the *impact categories* to be used, need to be stated, such as global warming potential (GWP), acidification and energy consumption (Ortiz *et al.*, 2009).

The second step involves the compilation and quantification of inputs and outputs for the *Functional Unit* throughout the life cycle. According to ISO 14044, LCI results are classified into impact categories (ISO, 2006b). These impacts can be evaluated based on midpoints and/or endpoint approaches. A midpoint approach is more related to elementary flows, which specifies the material or energy entering the system that has been drawn from the environment, without previous human transformation, or material or energy leaving the system that is released into the environment without subsequent human transformation (ISO, 2006b). On the other hand, an endpoint approach transmits relevant information about the characterization flows to the decision maker (Ismael, 2018). Midpoint indicators focus on environmental problems, such as global warming or acidification (Gernuks *et al.*, 2007). Endpoint indicators present the impacts of decisions made on human health, biodiversity and resource scarcity. The midpoint is also known as a problem-oriented approach, while the endpoint is designated as a damage-oriented approach (Gernuks *et al.*, 2007).

In the third step of LCA, the LCIA phase aims at understanding and evaluating the magnitude and significance of the potential environmental impacts. According to ISO 14040, LCIA is divided into five stages, of which two are mandatory and three are optional. The Classification and Characterization stages are mandatory, in which the elements of the LCI are attributed to one or more environmental impact categories, with each element then assigned to a value referring to its respective environmental

Fig. 1 Life cycle assessment framework. Source: Modified from ISO, 2006a. ISO 14040:2006 – Environmental Management – Life Cycle Assessment – Principles and Framework. doi:10.1136/bmj.332.7550.1107.

damage. The Normalization, Weighting and Aggregation steps in LCIA are optional stages. The results characterized can be normalized to make it possible to observe the most significant impact categories. They can also be weighted, which involves a subjective process where each category of environmental impact is assigned to an importance level. Thus, it is possible to make an aggregation, where the different categories of environmental impact can be aggregated into a single indicator to facilitate decision making.

The interpretation is the last phase of LCA. This step represents a technique for identifying and evaluating all the information from the other phases of the study, in relation to the defined goal and scope. This step is essential for the analysis, because practitioners must formulate conclusions and recommendations considering the uncertainties and lack of consistency in the LCI and LCIA phases. The professionals must analyze if the data quality is enough to achieve the goal of each study.

LCA Applied in Buildings

In the construction sector, LCA is an important tool to assist the assessment of the environmental performance of buildings. To achieve a more sustainable construction industry, it is advisable to use the LCA methodology in the early stages of project design and planning (Najjar *et al.*, 2017). This is because the cost of implementing changes increases as the project evolves, due to the reduction in flexibility of change (PMI, 2017). When performing environmental analyses at an early stage of the project, an opportunity exists to test and compare different types of materials and construction techniques, without this being too costly (Basbagill *et al.*, 2013).

It is important to note that a building is a complex structure, composed of different systems and components. Therefore, the building professional must make a great effort to obtain all the necessary data to perform the analysis. Oftentimes, the studies are not related to an entire building but are limited to individual elements of a building. This is because the size and complexity of a building makes it necessary for professionals to address some limitations in their studies (Lindberg *et al.*, 2004). These more specific studies have great value, but it is still necessary that the building be analyzed as a whole, going through all phases of its life cycle. This is the only way to ensure that construction achieves sustainable standards.

In addition to the importance of considering the whole building, it is ideal to consider all stages of the life cycle of the building. The building life cycle can be divided into eight main stages: (i) extraction of raw materials; (ii) manufacturing; (iii) distribution; (iv) construction; (v) operation; (vi) end-of-life; (vii) disposal; and (viii) recycling. These stages are represented in Fig. 2.

LCA applied to the construction sector has also become a useful tool for developing buildings that consume less resources, such as energy, water and fuel. About half of the world's electricity demand is consumed by the building sector (REN21, 2017). In addition, the construction industry is known to consume a significant amount of water and fuel throughout the project life cycle. When LCA is used to evaluate the energy consumed, all energy input can be accounted for throughout the life cycle, including both embodied energy and operating energy (Cabeza *et al.*, 2014). The same analysis can be done to quantify the consumption of water and fuel. Thus, when applying LCA in a construction project, other types of indicators can be considered in the analysis. It is important to quantify and analyze the consumption of resources, electricity, fuel, water and equipment. For example, to analyze the energy consumption during the operation phase of the building, it is necessary to calculate the energy use for heating, cooling, ventilation, hot water and lighting. Therefore, it is possible to consider the indicators for environmental impacts, known as LCIA impact categories, beyond the indicators for resource use and for other environmental information (EN, 2012).

When considering a building as an object of environmental analysis, it is also important to consider that several types of design decisions can influence the environmental impacts generated. Unlike other products that generate environmental impacts that depend only on the materials used and the manufacturing method employed, other factors need to be considered for building projects. This is because in the implementation of building LCA, it is also necessary to analyze the construction and operation phases, which contain services rather than construction properties (Erlandsson and Borg, 2003). A clear example of this is the location and orientation of the building on the ground. The designer should analyze the best position of the building to make the best use of natural lighting. This factor can drastically decrease the use of electricity over the years. In addition, configuring rooms in such a way to take advantage of natural ventilation can be an assertive decision to reduce the energy consumption produced by cooling systems.

Fig. 2 Life cycle of building projects.

When conducting a building LCA, one should evaluate not only the building, but also the external works attached to this building and temporary works associated with the building's construction. When the purpose of the analysis is the comparison of different alternatives, the definition of the *Functional Unit* is fundamental. In building LCAs, the *Functional Unit* can also be referred to as *Functional Equivalent*. This term refers to the quantified functional requirements and/or technical requirements for a building, to be used as a basis for comparison. The definition forms the basis for transparent and reasonable comparison between different types of buildings, permitting the practitioner to make the comparison qualified with a dimension like per m², per room, etc. (EN, 2012).

Limitations of LCA Application in Building Projects

Due to the great complexity of the buildings, many difficulties can arise during an LCA. It is imperative that professionals consider this complexity when performing a Building LCA. Otherwise, many aspects may be disregarded, and the results may not be representative.

The following will present some limitations present in performing building LCAs. These limitations exist in all types of buildings and should be thought of in all projects. It should be noted that each project is unique and that its particularities must be considered too.

Lifetime of the Buildings

In the construction sector, many LCA studies do not adequately address the actual lifetime of the buildings (Aktas, 2011). When assuming a typical value for the building lifetime, the study does not reflect the particularities of each project. For example, in one research study, the author found that existing service life prediction methods do not incorporate the effects of social factors into the analysis (Aktas, 2011).

Several factors can influence the building's lifetime, such as the materials and components that were used in the construction and the location of the building. In addition, the use of the building also interferes in this data. For example, it has been proven that lifetime of residential and commercial buildings is significantly different (Aktas and Bilec, 2012). This can be explained by the fact that commercial buildings need to be updated more quickly than residential buildings in order to get more economic benefits (Liu et al., 2014). The values need to be determined based on the nature of the construction, purpose, use and environment. One way to determine this value is to consider factors that can influence the lifetime of the building. An existing method, based on ISO 15686-1 (ISO, 2011), uses the following equation:

$$LFe = LFr \times f_A \times f_B \times f_C \times f_D \times f_E \times f_F \times f_G$$

Where:

LFe – Lifetime estimated;

LFr – Reference lifetime;

f_A – Materials quality factor;

f_B – Project quality level factor;

f_C – Execution quality factor;

f_D – Interior environment factor;

f_E – External environment factor;

f_F – Type of use factor;

f_G – Maintenance level factor.

There are already studies that point out the importance of determining with more precision the life span of buildings. One study presents an example of this, performing a statistical analysis that demonstrates that factors such as location, refurbishment, use type and wall material could potentially influence the quantification of the temporal scope of building LCAs (Østergaard et al., 2018).

It is therefore very important that the professional find a way to determine the lifespan of the building effectively. The use of a period of time that does not adequately address the actual lifetime may lead to misleading conclusions at the end of the study (Aktas, 2011).

Dynamic Parameters

The building data is characterized by time-dependent parameters which need to be evaluated (Lindberg et al., 2004). This is another challenge that needs to be addressed when conducting LCA.

The current LCA method considers arbitrarily fixed time horizons and/or steady state conditions (Shimako, 2017). But the concept of dynamic LCA, known by the acronym DLCA, is increasingly widespread among researchers. This concept transforms the LCA into a dynamic perspective, incorporating explicitly the dynamic modeling of processes in the context of temporal and spatial variations (Collinge et al., 2013). There are already several studies on this subject based on the building sector. One of these studies presents a methodology for applying this approach (Negishi et al., 2018). This work lists some dynamic parameters to buildings,

such as energy consumption, the typology of inhabitants and their behavior. These parameters can be variable depending on the economy, culture and climate.

Dynamic LCA can help decision makers improve their understanding of when and in which context potential impacts occur (Fouquet *et al.*, 2015). But certainly, its application is not carried out so easily. There is still much to study on the subject, so that all time-dependent parameters can be considered. Applying this approach requires the practitioner to have a large amount of data. In addition, it becomes necessary to analyze both quantitative and qualitative data at the same time, which can lead to even more uncertainties in the analysis.

Despite the difficulties, it is fundamental that the dynamic nature of projects be taken into account when performing a Building LCA. Considering these dynamic parameters is paramount for more assertive environmental assessments. Ignoring the nature of the data may render the analyses unreliable and nonrepresentative of the reality of the construction project.

Difficulties in Proposing Modifications

To make use of all the potential of the LCA approach on buildings, it is important to compare different materials and resources in the same project in order to choose the more sustainable list of materials in each case. However, making these changes can mean a substantial increase in the work of designers. It is estimated that about 60% of the time is being lost in the early stages of designing construction projects. This is justified by the need to insert repeated information in the model, in order to test the existing alternatives (Najjar *et al.*, 2017). To solve this issue, it is advisable to use a software based on Building Information Modeling (BIM) to create building projects.

For BIM, information is the core of modeling. The three-dimensional model is a real prototype of the building. With this technology, the insertion of all the necessary information associated with the planning of a building is made in a single digital model, allowing, thus, a better management of the whole project (Figueiredo, 2018).

The modeling process is performed parametrically, that is, all elements are represented by parameters that are associated with data. This allows a constant updating of the project, carried out in a dynamic fashion. Besides that, it is important to emphasize that BIM methodology is not limited to the geometric parameters, such as thickness, length and height of objects, present in design or engineering drawings (Jung and Joo, 2011). In fact, the methodology uses a digital model that can be extended for multiple purposes. It is possible, for example, to specify thermal and acoustic properties of the materials used, as well as to consider climatic data of the geographic region. Based on BIM, it is easier to perform simulations in order to critically analyze the building.

The integration of BIM and LCA methodologies in the design phase of the project has great potential in terms of influencing the project (Figueiredo, 2018). With efficient information management, it is possible to design projects that consider environmental aspects. Therefore, it is strongly advised that professionals invest in this integration so that they can consider a large part of the building data.

Uncertainty and Variability

As the time available to develop a building project reduces, it is necessary to also reduce the data collection effort and to make input simplifications and assumptions; this could however result in misleading conclusions (Pannier *et al.*, 2018). Thus, many uncertainties are created and need to be considered in the interpretation of LCA results (Hoxha *et al.*, 2017).

Among other sources of uncertainty, two deserve special attention due to their ability to compromise the reliability of LCA results: poor data quality and the exclusion of site-specific data from the inventory (Ross *et al.*, 2002). There are already computer programs focused on performing LCA in buildings that integrate BIM and LCA methodologies, such as Tally™ (Kieran Timberlake Innovations, 2018) and Impact™ (BRE Group, 2019). Although there are already applications and software for this purpose, they do not present the possibility to perform a Sensitivity Analysis (SA) of the results.

Sensitivity analysis seeks to determine the effect of a variation of a given item on the total impact assessed for that item. Once the professional restricts the data collection, it is necessary to fully understand what consequences will be faced. A sensitivity analysis is essential for the interpretation phase, so that the LCA practitioner can make the best conclusions and recommendations for the project.

The Complexity of Decision Making

The methodologies focused on the life cycle concept allow quantifying various types of impacts. However, the implementation of these techniques increases the complexity of decision making and therefore requires systematic tools and methods (Gaudreault *et al.*, 2009). In this context, Multiple-criteria decision-making (MCDM) and LCA approaches complement each other well.

MCDM is an approach used to aid in the decision-making process, allowing to analyze the problem from different points of view and considering different alternatives. There are many methods in the scientific literature to support strategic decision making, such as mathematical optimization (Hammad *et al.*, 2016, 2018), fuzzy set theory (Onat *et al.*, 2016), and the analytic hierarchy process (Ahmad and Tahar, 2014). Yet there is no method which is known to be the most appropriate as it would depend on the setting in which the project case is considered, along with the information that is available.

It is becoming more recurrent to find studies that use MCDM to contrast between environmental and economic outcomes. A study carried out in 2017 surveyed the existing studies developing or implementing different methods for combining environmental and economic analysis of products, technologies and systems (Miah *et al.*, 2017). This is interesting to understand the progress of using MCDM to integrate life cycle analysis approaches. The authors reported that 30 studies conducted between 1999 and 2016 used MCDM to integrate Life cycle assessment and life cycle cost. Of these, 6 are related to building projects. There were also 32 studies, between 2002 and 2016, in which environmental and economic analysis is taken as an optimization problem. Among these studies, 10 are about buildings.

However, most studies that use MCDM are still focused on comparing financial and social aspects. Much progress still needs to be made in the field on the integration of MCDM and LCA. In order to make a good environmental decision, it is necessary to first choose the importance weights for each impact category considered. This choice is subjective as it will depend on the preferences of the decision maker and therefore can vary from one decision maker to another. This is one of the many challenges that must be addressed, but the study on the integration of these methodologies needs to be encouraged.

Challenges and Way Forward

As previously explained, applying the LCA methodology to building projects is still a major challenge for professionals. A building is composed of several systems and it is necessary to obtain a large number of data for a reliable analysis. As a result, this research explores the possibility of utilizing an integrated platform that combines other methodologies, as shown in Fig. 3. The purpose is not to define a more appropriate method for the analysis of construction projects, but to present a possibility of integration between methodologies that together have the capacity to transform buildings projects into more sustainable ones.

As explained graphically in Fig. 3, the idea is to use the LCA methodology concomitantly with other methodologies to obtain more accurate results. Following the basic principles of LCA, it is advisable for practitioners to perform the following design steps:

- Use statistical analysis to determine more accurately the lifetime of the studied building;
- Adequately evaluate time-dependent parameters based on the concept of dynamic LCA (DLCA);
- Analyze a digital prototype of the building based on BIM, which embeds parameters that generate different simulations;

Fig. 3 Integration of methodologies.

- Make use of some MCDM method to aid in the decision making of the project, in order to make the most environmentally conscious choices;
- Conduct a sensitivity analysis to aid in the interpretation of the results obtained.

Thereby, the concept of sustainability in buildings becomes feasible, since the entire life cycle of the building is analyzed in the project planning phase. This allows practitioners to test different alternatives within the building to make more assertive decisions that save energy and water and generate less environmental impacts.

Unfortunately, there is not yet a commercially available platform that gathers all these concepts together, but this development is encouraged by the authors. Such an integration would be a multidisciplinary tool, as it would encompass several areas of knowledge. This requires great knowledge of the team of professionals, as well as requiring more time in the design phase of the construction project. It is thus necessary to encourage research in this area, exploring the use of the proposed framework in real buildings. Finally, it is hoped that the analysis of the social and economic impacts will also be incorporated, so that sustainable construction can be achieved, covering all the main pillars of sustainability.

Introduction

Activated carbon (AC) is a versatile porous material with the high surface area and high pore volume. It has a wide variety of practical applications such as gas storage (Sheikh *et al.*, 1996; Lozano-Castello *et al.*, 2002; Rahman *et al.*, 2010; Thu *et al.*, 2014), separation (González *et al.*, 2013; Cong *et al.*, 2015), adsorption cooling (Pal *et al.*, 2016, 2017a,b), hydrogen storage (Jordá-Beneyto *et al.*, 2007; Xu *et al.*, 2007), methane storage (Rahman *et al.*, 2010) CO₂ capture (Himeno *et al.*, 2005; Jin *et al.*, 2011; Yu *et al.*, 2015; Kayal and Chakraborty, 2018), and super-capacitor applications (Xing *et al.*, 2006; Wen *et al.*, 2009; Di Biase and Sarkisov, 2013). However, the ACs used in the above applications are expensive and made from non-renewable precursor materials such as coke and petroleum residue (Otowa *et al.*, 1993). On the other hand, there are plenty of renewable precursor sources which can be used for ACs preparation using various techniques. Renewable biomass precursors usually grow through the agricultural activities, and it contains chemical constituents having high carbon content which is beneficial for ACs production. Using biomass as a precursor is termed an environmentally benign approach as it prevents the production of CO₂ and CH₄ during conversion and the byproducts finally enter the natural carbon cycle process. Recently, numerous research works have been reported where ACs are prepared from a different source of waste biomass as it is renewable and cheap (Yang *et al.*, 2010; Hao *et al.*, 2013; Bhatnagar *et al.*, 2015; Mahamad *et al.*, 2015; Jain *et al.*, 2016; Kyzas *et al.*, 2016; Sahoo and Ramgopal, 2016). Danish and Ahmad (2018) reviewed the usage of wood biomass as a sustainable precursor to synthesize ACs where authors cited different agricultural sources for the production of low-cost ACs. Coconut shell-based ACs were prepared using activating agents such as steam, CO₂ and a mixture of steam-CO₂ with microwave heating (Yang *et al.*, 2010). Kyzas *et al.* (2016) explored the use of ACs from waste potato peels using phosphoric acid at different activation temperatures such as 400, 600 and 800°C. The ACs were prepared by Hao *et al.* (2013) from hydrothermally carbonized waste biomass for CO₂ capture from flue gas. Mahamad *et al.* (2015) synthesized ACs from the pineapple waste biomass (leaves, stem, crown) using ZnCl₂ as an activating agent. Nor'Azizi Bin Othman (NOR', 2013) synthesized the ACs from waste palm trunk (WPT) using KOH and steam as an activating agents.

Literature review indicates that biomass is a good choice as precursor materials but the porous properties of the biomass-derived ACs reported so far are not optimized. There is a scope to increase surface area and pore volume if the optimum condition is applied during the carbonization and activation process. Therefore, the aim of this study is to obtain excellent surface area and pore volume contained ACs by optimizing the synthesis process. This article presents the synthesis process of ACs from two kinds of biomass namely waste palm trunk (WPT) and mangrove (M). Some important contributions in this article are:

- Mechanism of activated carbons production from biomass precursors are presented.
- Chemical activation method at different activation conditions is experimentally investigated after carbonization of raw biomass (waste palm trunk and mangrove) to synthesize highly porous ACs.
- Potassium hydroxide (KOH) with different mass ratios is used as an activating agent for chemical activation.
- A series of ACs are prepared from WPT and M by changing the activation conditions.
- Dried, carbonized and activated yield sample are presented at every synthesis condition.
- Surface morphology and elemental composition of synthesized ACs are investigated.

Sample Preparation

Precursor Material

The properties of a precursor material considerably influence the nature of the resulting yield. The chemical nature of the surface oxides and the surface area of the AC are determined by carbonization and activation method whereas the pore size distribution and the pore structure are mostly determined by the nature of the precursor material and the extent of activation (NOR', 2013). In this article, waste palm trunk (WPT) and mangrove (M) are employed as a low cost and renewable precursor materials for the production of ACs that can be used in

Fig. 1 Pictorial view of two kinds of raw biomass employed for synthesis.

Table 1 Elemental composition of waste palm trunk (WPT) and mangrove (M)

Raw material	Elemental composition [wt%]				Ash [wt%]
	C	H	N	$O_{diff.} [100\% - \sum (C, H, N, Ash)]$	
WPT	44.02	5.75	0.49	48.41	1.33
M	46.70	6.04	0.14	45.98	1.14

various applications such as adsorption heat pump (AHP) systems, CO₂ capture or storage, and energy storage. **Fig. 1** shows the pictorial view of two kinds of biomass that are used as precursors. From the photograph, it can be seen that the WPT and M are structurally different from each other. As a result, both materials may produce different surface area, surface morphology, pore volume, and pore size at different carbonization and activation conditions, as initially expected. Elemental composition of raw samples (WPT and M) are analyzed using a CHN (Carbon, Hydrogen, and Nitrogen) analyzer (MT-5, Yanako, Japan). The assessment of O content ($O_{diff.}$) can be defined by subtracting the sum of the contents of C, H, N, and ash from 100%. The elemental composition of raw WPT and M is shown in **Table 1**. The carbon contents of raw WPT and M are found 44.02% and 46.70%, respectively.

The N₂ adsorption/desorption isotherm and pore size distribution (PSD) of two raw biomasses are shown in **Figs. 2** and **3**, respectively. The N₂ adsorption amount onto both biomasses is low which implies that raw material possesses low surface area and pore volume. However, WPT shows high adsorption capacity of N₂ compared to M. The PSD results show that WPT has a wide range of pore size distribution compared to M. Furthermore, the total pore volume is higher than that of mangrove. The BET report including surface area and pore volume of two raw biomasses are furnished in **Table 2**.

Carbonization of Biomass Precursor

The main purpose of carbonization or pyrolysis is to remove the volatile substances from the biomass in order to convert into a suitable form for activation. It is usually performed in an inert atmosphere. Nitrogen (N₂) is commonly used as an inert gas during the carbonization and activation process because it can repel the gaseous oxygen (O₂) from the pyrolysis chamber. Thus, the burning of the biomass can be avoided. Furthermore, N₂ gas is clean, comfortable to handle, and available at low-cost. During the phase of the carbonization, the carbon content of the product reaches a value of more than 65 per cent and possesses an elementary pore structure. Most of the non-carbon elements, hydrogen, and oxygen are removed in gaseous form during the carbonization process. It consists of four main steps ([Rashidi and Yusup, 2017](#)):

Fig. 2 N_2 adsorption/desorption isotherm of two biomasses, WPT and M.

Fig. 3 Pore size distribution of raw WPT and M: (a) incremental; (b) cumulative pore volume.

Table 2 BET report and pore volume of waste palm trunk (WPT) and mangrove (M)

Parameter	WPT	M
BET surface area [$m^2 g^{-1}$]	130 ± 4	43 ± 3
Slope [$g cm^{-3}$]	0.023767 ± 0.000920	0.073269 ± 0.007433
Y-intercept [$g cm^{-3}$]	0.009596 ± 0.000274	0.027351 ± 0.002521
C [dimensionless]	3.476699	3.678805
Q_m [$cm^3 g^{-1}$]	29.9732	9.9383
Correlation coefficient [dimensionless]	0.9940621	0.9948941
Molecular cross-sectional area [nm^2]	0.1620	0.1620
Total pore volume [$cm^3 g^{-1}$]	0.13356	0.04146

Step 1: dehydration process occurs at a temperature lower than $200^\circ C$ in which moisture from the raw material is removed.
 Step 2: at a temperature range of 170 – $270^\circ C$, the biomass starts to decompose while light tar and organic acid are discharged.
 Step 3: the biomass is decomposed, and a significant amount of liquid and gas is released to produce bio-char at temperature 270 – $350^\circ C$.
 Step 4: temperature above $350^\circ C$, an acceleration in carbon content occurs by removing the remaining volatiles.

Fig. 4 Crushing and drying samples: (a) WPT and (b) M.

Fig. 5 Preparation steps for biomass-derived ACs. Reproduced from NOR', A.B.O., 2013. Effective utilization of waste palm trunk. Kyushu University. Available at: <http://hdl.handle.net/2324/462781> (accessed 02.04.18).

The precursors are essential to undergo a pre-treatment process before carbonization. According to the literature, pre-treatment procedure includes several phases: (a) washing, (b) drying, and (c) crushing and drying. In this experiment, WPT and M are crushed into a particle size less than 5 mm in order to perform homogeneous drying and carbonization. The crushing samples are then dried in an air dryer at 100°C for 48 h. The vacuum drying at 105°C for 1 h is accomplished after air drying before being used for carbonization. These two drying operations assist for removing water or moisture content from the biomass. The photograph of the crushing and drying of two kinds of biomass is shown in Fig. 4. The carbonization process for both biomasses is carried out at 500 and 600°C at a heating rate 10°C/min with N₂ flow rate 100 cc/min for 1 h. The sample preparation scheme of ACs from biomass is shown in Fig. 5 (NOR', 2013). The carbonization reactor chamber is shown in Fig. 6. The chamber mainly consists of the high-temperature furnace with a temperature controller, stainless steel tube, and N₂ gas tank. The rotameter is used to control the N₂ flow

Fig. 6 Schematic diagram of an experimental setup for carbonization and KOH activation process.

Fig. 7 Photograph of carbonized samples: (a) WPT and (b) M.

rate inside the reactor chamber. **Fig. 7** shows the photograph of two carbonized biomass samples. After the heat treatment, biomass-derived carbonized samples are grinded and sieved to mesh size 100 μm for the application to the adsorption heat pump systems.

The resulting carbonized samples have a small adsorption capacity, which is not suitable for adsorption applications. To enhance the adsorption capacity, the activation process is conducted (Section "Activation of Carbonized Biomass Sample") in turn to increase the surface area and pore volume of the ACs.

Activation of Carbonized Biomass Sample

The ACs are mostly prepared using two activation methods: physical activation and chemical activation. Porous properties including surface area and pore structure depend on activation method along with inherent properties of precursor material. Before activation process, carbonized material is required to undergo several stages: (a) drying, (b) grinding, and (c) sieving to preferred size.

Physical activation

In physical activation, the reaction is involved between a carbon atom and the oxidizing gas such as steam, carbon dioxide (CO_2), a binary mixture of CO_2 and nitrogen (N_2), or air at an elevated temperature ranging from 800 to 1100°C. This method can produce ACs with well-developed pore structure. However, the surface area of the prepared ACs is comparatively lower than that of the chemical activation. The physical activation method is considered an inexpensive and environmentally benign process because of the absence of a chemical agent that may create a subsequent disposal problem. However, prolonged activation time together with low carbon yield, and high power consumption are disadvantages of this process (Rashidi and Yusup, 2017). The reaction mechanism for the gas activation of carbon with steam or CO_2 can be characterized by the following several simultaneous/consecutive reactions (Eqs. (1)–(3)). **Fig. 8** shows a schematic drawing of the experimental setup for steam activation. It mainly consists of a high temperature electric furnace, tape heater, N_2 gas, quartz tube, rotameter, valve, water bath for the steam generator, and a cooling bath.

Fig. 8 Schematic drawing of the experimental setup for steam activation.

Chemical activation

The various kinds of activating agents including potassium hydroxide (KOH), sodium hydroxide (NaOH), potassium carbonate (K_2CO_3), phosphoric acid (H_3PO_4), sulfuric acid (H_2SO_4), and zinc chloride ($ZnCl_2$) are usually employed in chemical activation process (Rashidi and Yusup, 2017). Consequently, different chemical agents react differently with the precursors and hence influence the development of porosity, pore structure, and adsorption behavior. This activation is economically feasible compared to physical activation because it requires lower activation temperature, shorter processing time, and gives high carbon yield. However, in this activation process, the sample required washing at the final stage to remove the residual inorganic material which may cause a pollution problem.

In this article, carbonized WPT and M are used as a precursors for preparing ACs by applying chemical activation method. The particle size less than $100 \mu m$ of these two carbonized samples is used for the activation. The activation process is carried out in a nitrogen (N_2) atmosphere which creates an inert atmosphere. The identical activation conditions are applied to both carbonized materials (WPT and M). Fig. 5 represents the processing steps for preparation ACs from raw biomass (NOR, 2013). The chemical activation of various carbon sources using KOH as an activating agent is very promising because of its lower activation temperature and higher yields, and well-defined micropore size distribution and ultrahigh specific surface area up to $3000 m^2 g^{-1}$ of the resulting ACs (Otowa et al., 1993; Tay et al., 2009; Wang and Kaskel, 2012). The same experimental setup (Fig. 6) is used for the preparation of ACs using potassium hydroxide (KOH) as an activating agent. The KOH (purity > 85.0%, Wako Pure Chemical Industries, Ltd.) is selected as an activating agent in the impregnated WPT and M biochar because it is found to be more effective than another chemical agent such as $ZnCl_2$ and H_3PO_4 for creating porosity in ACs. The experimental conditions of temperature, activating agent (KOH), heating rate, holding time, N_2 flow rate are the same for preparation of ACs from both carbonized materials of WPT and M. The chemical activation process using KOH as an activating agent consists of several possible simultaneous/consecutive reactions proposed by several researchers (Otowa et al., 1993; Wang and Kaskel, 2012), which are shown in the following equations.

The chemical reactions presented in the Eqs. (4)–(7) occur at activation temperature lower than $700^\circ C$. A considerable amount of metallic potassium is formed by the reduction of K_2O by carbon and hydrogen when the temperature exceeded $700^\circ C$.

Table 3 Series of AC samples synthesized from WPT and M by changing carbonization and activation conditions

^aW: Waste palm trunk (WPT); M: Mangrove; C: Carbonization temperature in °C (for example: C500 means carbonization at 500°C); A: Activation temperature in °C (for example: A600 means activation at 600°C); K4 and K6: 4 and 6 times KOH of carbonized sample.

Table 4 Water content of waste palm trunk (WPT) and mangrove (M)

Sample	Air drying		Vacuum drying		Water content		
	Temperature [°C]	Drying time [h]	Temperature [°C]	Drying time [h]	1st experiment [wt%]	2nd experiment [wt%]	Average [wt%]
WPT	100	48	105	1	8.64	9.32	8.98
M					7.53	7.55	7.54

Based on the above observation, Wang and Kaskel (2012) reported the following three main possible activation mechanisms for KOH activation of carbon.

- (1) Etching the carbon framework by the redox reactions between various potassium compounds with carbon as shown in Eqs. (8), (11), and (12), called chemical activation, are responsible for generating the pore network.
- (2) The formation of H₂O (Eq. (4)) and CO₂ (Eqs. (6) and (9)) in the activation process positively contributes to the further development of the porosity through the gasification of carbon, namely physical activation (Eqs. (5) and (10)).
- (3) The metallic K produced by carbon reduction of K compounds (K₂O and K₂CO₃) as shown in Eqs. (8), (11), and (12), efficiently intercalating into the carbon lattices of the carbon matrix during the activation, results in the expansion of the carbon lattices. After the removal of the intercalated metallic K and other K compounds by the washing of HCl and DI water, the expanded carbon lattices cannot return to their previous nonporous structure, and thus the high microporosity is created.

In this article, the effects of various preparation conditions, including different activation temperatures (600–900°C), the impregnation ratios of KOH/WPT or M biochar (4:1 and 6:1) are studied in order to establish the optimum condition for producing high adsorption ability, large surface area with micropore, and large pore volume of ACs. The activation process can be explained as follows (Pal *et al.*, 2017a): firstly, the weight ratio of KOH/carbonized biomass is set to 4 or 6 and put into the stainless steel container. The KOH and carbonized biomass are then mixed inside the container. After that, the stainless steel container is placed into an electric furnace vertically. The mixture is heat-treated up to 600°C at a heating rate of 5°C/min and maintained at 600°C for 1 h under N₂ flow rate 100 cc/min. After the activation, the remaining KOH and salts formed during the heat treatment are removed by the washing with HCl solution for three times and deionized water once to adjust pH to be about 7. Finally, the collected samples are dried at 100°C for 3 h in an air oven and dried again at 150°C for 12 h in a vacuum oven. A similar procedure is applied to other several activation temperatures. Total 12 samples, six from each type of biomass (WPT and M) are prepared as can be seen in Table 3. The synthesized ACs are then characterized using the investigation of scanning electron microscopy (SEM) image and elemental composition.

Yield of Processed Sample

Yield of Dried Raw Biomass

Table 4 shows the results of water content in raw WPT and M after air drying 100°C for 48 h and vacuum drying at 105°C for 1 h. After completing two consecutive drying processes, it is found that the average water content of WPT and M are 8.98 wt% and 7.54 wt%, respectively. It can be said that water content in WPT is relatively higher than that of M.

Table 5 Yield of carbonized product of WPT and M at carbonization temperature 500°C

Sample	No. of experiments and yield [wt%]					Temperature [°C]	Heating rate [°C/min]	Holding time [h]	Average yield [wt%]
	1	2	3	4	5				
Carbonized WPT	30.41	30.88	30.71	30.95	30.09	500	10	1	30.61
Carbonized M	31.96	31.94	31.60	31.62	31.36				31.70

^aW: Waste palm trunk (WPT); M: Mangrove; C: Carbonization temperature in °C (for example: C500 means carbonization at 500°C); A: Activation temperature in °C (for example: A600 means activation at 600°C); K4 and K6: 4 and 6 times KOH of carbonized sample.

Fig. 9 SEM images of carbonized WPT at 500°C.

Yield of Carbonized Sample

Efficiency of carbonization is expressed in terms of yield production as a percentage of biomass used to produce it. The conversion yield depends on the moisture content of the biomass during carbonization and the carbonization temperature. The yield of carbonized sample derived from the dried WPT and M is shown in Table 5. The carbonization process is carried out at 500 and 600°C at a heating rate of 10°C/min and maintained at 500°C or 600°C for 1 h at N₂ flow rate 100 cc/min. The average yield of carbonized WPT and M for 500°C are 30.61 wt% and 31.70 wt%, respectively. From the results, it can be concluded that M shows a relatively higher yield compared to WPT.

Yield of Activated Carbon Sample

The activation yield of produced ACs derived from carbonized WPT and M is summarized in Table 6. From the results, it can be seen that at low temperature and the low weight ratio of KOH gives higher yield. In the case of WPT-derived ACs, the activation temperature 600°C and four times KOH shows the highest yield, which is about 50.17 wt%. On the other hand, the activation temperature of 900°C and six times weight ratio of KOH produced the lowest yield which is about 20.54 wt%. The M-derived ACs show a similar trend but produces a higher amount of yield. The activation temperature 600°C and four times KOH produced the highest yield, which is 54.61 wt% whereas activation temperature 900°C and six times weight ratio of KOH gives the lowest yield which is about 32.14 wt%. It can be noted that M-derived ACs give higher activation yield compared to the WPT-derived ACs.

Surface Morphology

Figs. 9 and 10 show the scanning electron microscopy (SEM) images of carbonized WPT and M samples at 500°C, respectively. It can be seen that inherently both biomasses possess various kinds of structures. The both WPT and M possess the canal structure,

Fig. 10 SEM images of carbonized M at 500°C.

Fig. 11 SEM images of WPT-derived ACs (a) WC500A600K4; (b) WC500A700K4; (c) WC500A800K4; (d) WC500A900K4; (e) WC500A900K6, and (f) WC600A900K6.

which is an excellent texture for ACs production as the activating agent can easily diffuse into the carbon micropores and develop a large surface area and pore volume. During the carbonization, most of the non-carbon elements remove with the basic skeleton of the polymer remaining, which produces biochar retaining the shape of the biomass precursor and formed the initial porosity of the biochar.

The porous structure and chemical nature of ACs depend on the precursor materials, activation methods, and the extent of activation. This is the reason why surface area or pore volume of ACs differ widely from one kind to another. The pore structures of all synthesized AC samples are investigated by scanning electron microscope (SEM). The SEM images reveal the changes in morphology in the AC samples during the activation process. **Figs. 11** and **12** represent the morphology of all WPT and M-derived ACs synthesized from various activation conditions. The synthesized ACs preserve their micro-structural feature even at severe conditions as can be seen from SEM images.

Elemental Composition (CHN) Analysis

The carbonized products are produced from natural starting materials of WPT and M. The elemental composition (Carbon, Hydrogen, and Nitrogen) are analyzed using Yanaco CHN Corder (MT-5) manufactured by Yanagimoto Mfg. Co., Ltd. The CHN analysis method is based on differential thermal conductivity method. A sample of amount 800 μg is used for this experiment. The ultra-micro balance (Mettler Toledo XPR2U) is employed to measure the sample weight and the remaining amount after the experiment. At first, the sample is entirely burned under the flow of He with O_2 gas at a combustion furnace where CuO is filled. So, the sample is converted to CO_2 , H_2O , NOx gases, and others. Among them, NOx gas is reduced to N_2 by Cu at a reduction furnace. The other gases except for H_2O , CO_2 , and N_2 are removed by absorbers in combustion or reduction furnace. H_2O , CO_2 , and N_2 gases are detected by each thermal conductivity detector as counter signals. Finally, they are converted to the content of mass percentage. Typically, a carbonized product comprises high carbon content about 65%–90% which mostly depends on the inherent properties of precursor material. **Table 7** shows the elemental composition of carbonized WPT and M at two different carbonization temperatures, 500 and 600°C. The carbon content increases after the carbonization in both samples. It is observed that the carbon content for 600°C carbonization temperature is higher than that of 500°C for both precursor materials. It is found that the carbonized M sample possesses higher carbon and low ash content compared to the WPT. Actually, the high carbon and low ash content of carbonized materials are suitable for making ACs. The assessment of O content (O_{diff}) can be defined by subtracting the sum of the contents of C, H, N, and ash from 100%.

Table 8 represents the elemental composition of selected ACs to understand the effect of activation condition. It is observed that activation process increases the carbon content and decrease the ash content as expected. The higher activation temperature and KOH

Fig. 12 SEM images of M-derived ACs (a) MC500A600K4; (b) MC500A700K4; (c) MC500A800K4; (d) MC500A900K4; (e) MC500A900K6, and (f) MC600A900K6.

Table 7 Elemental composition of carbonized WPT and M

Sample	Elemental composition [wt%]				Ash [wt%]
	C	H	N	$O_{diff.} [100\% - \sum (C, H, N, Ash)]$	
WPT (C500)	66.59	2.56	0.39	26.14	4.32
WPT (C600)	69.68	1.79	0.39	19.14	9.00
M (C500)	73.85	3.09	0.21	19.91	2.94
M (C600)	79.92	2.22	0.20	14.56	3.10

Table 8 Elemental composition of AC samples derived from WPT and M

Sample	Elemental composition [wt%]				Ash [wt%]
	C	H	N	$O_{diff.} [100\% - \sum (C, H, N, Ash)]$	
WPT (C500A600K4)	79.25	1.27	0.20	18.81	0.47
WPT (C500A900K6)	90.78	0.09	0.12	8.82	0.19
M (C500A600K4)	79.95	1.25	0.10	18.70	Not detectable
M (C500A900K6)	94.28	0.19	0.09	5.44	Not detectable

ratio also increase the carbon content and decrease the ash content. This is true for both sample as can be seen from [Table 8](#). The M-derived ACs show high carbon and no ash content. It is highlighted that carbon content increases to more than 90 wt% and minimizes the ash content after activation for both biomass-derived AC samples which is promising for various gas adsorption applications.

Conclusions

In this article, a series of activated carbons are synthesized from two waste biomasses, namely, waste palm trunk and mangrove. The detail synthesis process is presented which shows that carbonization temperature between 500 and 600°C are optimum to

obtain the ACs with high carbon and yield content. At this temperature almost 100% of all volatile matters and tars remove from the sample. It is found that dried WPT and mangrove give a yield of 30 wt% or more in the carbonization process at temperature 500°C at a heating rate of 10°C/min for 1 h. By KOH activation, biomass-derived ACs produced 20–50 wt% of yield. Particularly, M-derived ACs produced higher yield compared to WPT. It is observed that the carbon content is higher for 600°C carbonization temperature than that of 500°C for both precursor materials. The carbonized M sample possesses higher carbon and low ash content compared to the WPT. The synthesized ACs maintain their micro-structural feature even at high temperature and KOH ratio. The ACs derived from both biomasses contain various types of porous structures. It can be concluded that waste palm trunk and mangrove could be very promising precursors for synthesizing ACs with excellent physical properties. In addition, utilizing biomass as a precursor for synthesizing the ACs is considered as a wise approach since it can avert the production of CH₄ and CO₂. The porous properties, thermal conductivity, gas adsorption capacity are experimentally studied and presented in the next article to manifest its superiority over other ACs. The biomass-derived ACs could be the best choice for various applications including adsorption heat pumps and CO₂ capture or storage.

Synthesis, Characterization and Applications of Nano-Structured Sol-Gel Coatings

Shimaa M Ali, Cairo University, Giza, Egypt

© 2020 Elsevier Inc. All rights reserved.

Introduction

The relationship between the two words “nano” and “sol-gel” can take several forms, for example nanomaterials can be prepared through a sol-gel process where a variety of shapes can result, allowing the possibility of use in many useful applications (Caruso and Antonietti, 2001). The sol-gel process is a wet-chemical process that used to prepare ceramic nanomaterials. A solution of a metal precursor undergoes hydrolysis or polycondensation reactions to form a colloid or a gel. Then a proper thermal treatment is applied to enhance crystallinity and mechanical properties. Another possible example is the nanocoating, where a sol-gel layer of a nanoscale thickness is prepared on a given substrate (Sepeur and Frenzer, 2014). Coating can enhance the substrate properties by increasing its chemical, thermal, or mechanical stability. Several routes can be used for applying a nanocoating such as plasma-assisted technique, pulsed laser deposition, magnetron sputtering, etc. It is clear that sol-gel layers of nano thickness are not easily prepared and hence, require advanced techniques. The nanocoating definition can also be applied to sol-gel coating with thickness less than 3 μm , containing nanoparticles or nanomoieties. This article focused on the last type and includes the synthesis route of the nanoparticles/sol-gel coatings, characterization techniques, and some of its common applications such as, corrosion protective, scratch-resistant, transparent, catalytic, and bioactive coatings.

Synthesis of Nano-Structured Sol-Gel Coatings

Silica alkoxides are the most frequently used precursors for the inorganic network sol-gel synthesis. Other metal alkoxides, such as titanium, zirconium, aluminum, and zinc alkoxides, can also be added to obtain hybrid coatings with enhanced properties. It was found that Si-M (M is Ti, Zr, Al, or Zn) based hybrid inorganic-organic sol-gel coatings possess better adhesion to substrates, offer enhanced “bridge” effect between inorganic and organic phases (Suriano *et al.*, 2017), and have a pore blocking effect in the coating. The formation of these metal oxides nanoparticles has been noticed upon sol-gel synthesis (Rodric *et al.*, 2016). These nano oxides add more benefits to coating properties and hence diverse its applications. TiO_2 and ZrO_2 have good chemical stability and thermal resistivity making it promising materials for corrosion protection (Ali and Al Ishaibi, 2017; Balaji and Sethuraman, 2016), whereas, TiO_2 is less expensive and exhibits higher efficiency permits its use in semiconductors solar cells (Merazga *et al.*, 2016). Al_2O_3 has lower electron conductivity which is perfect for corrosion protective coatings (Tiwari *et al.*, 2011). ZnO_2 has lower dielectric constant, higher chemical stability, large band gap energy, facilitating its applications in coatings, sensors, solar cells, etc., (Ivanovaa *et al.*, 2018).

Cambon *et al.* (2012) have prepared a hybrid sol-gel coating containing Al_2O_3 by mixing glycidoxypopyl-trimethoxysilane (GPTMS), aluminum tri-*sec*-butoxide, distilled water and propanol with molar of ratio 5:1:1:10. Then the sol is stirred for 2 h at room temperature before being coated on a stainless-steel substrate by dip coating technique. In such a way, both Si and Al precursors are hydrolyzed and condensed simultaneously at a single step to form a sol-gel material containing nano Al-moieties or nano Al_2O_3 . On the other hand, successive and consecutive synthesis steps have been reported by Tiwari *et al.* (2011). At first, the silica sol is prepared by mixing tetraethyl orthosilicate (TEOS) with ethanol and distilled water in a ratio of 4:5.5:90.5 (v/v), and stirring for 10 min. A steel substrate is dip-coated in the silica sol followed by dipping in 0.4 M aluminum oxy-hydroxide solution, calcination at 500°C for 2 h results in a conversion coating layer on the steel substrate. Finally, steel substrate coated with the conversion layer is dipped in Al_2O_3 sol prepared by the hydrolysis and polycondensation of aluminum isopropoxide catalyzed by HNO_3 . Another possible synthetic route is to add a given weight of alumina nanoparticles to the silica sol (Alongi and Malucelli, 2013).

Balaji and Sethuraman (2017) have prepared a hybrid TiO_2 /sol-gel nanocomposite coating by mixing hybrid sol with nano- TiO_2 sol. The hybrid solution is formed by mixing 0.1 M GPTMS and 0.1 M TEOS (3:1) with stirring for 2 h, HCl is added to promote hydrolysis and condensation reactions. While, nano- TiO_2 sol is prepared by mixing 0.1 M titanium (IV) isopropoxide and ethylacetoacetate, as a chelating agent (1:1) and stirring for 15 min. Finally, nano- TiO_2 sol is added into hybrid sol (1:1) with constant stirring. Shanaghi *et al.* (2017) have enhanced the barrier properties against corrosion of silica-titania hybrid coating by silver doping. Ag-doped silica-titania solution has been prepared by using TEOS, butyl orthotitanate, and silver nitrate with 98% ethanol as the solvent, ethylacetoacetate as a chelating agent, and 65% nitric acid as a catalyst to promote hydrolysis and condensation reactions, as shown in Fig. 1.

Hybrid zirconium nanocomposite based sol-gel coatings have been prepared by Balaji and Sethuraman (2016) and doped with thiourea and its derivatives. The hybrid sols were prepared by hydrolysis and condensation of GPTMS, TMOS and tetra-*n*-propoxyzirconium (TPOZ) in acidic solution, followed by the impregnation of thiourea and its derivatives, as shown in Fig. 2.

A mixed zirconia/silica coating can be also prepared by mixing two different solutions, prepared separately due to the different hydrolysis rates of silicon and zirconium alkoxides (Castro *et al.*, 2005; Suriano *et al.*, 2017). The first solution is prepared by mixing TEOS: Ethanol: Water: Hydrochloric acid (1:4.5:3.5:0.07), under stirring for 1 h to permit hydrolysis and condensation of TEOS. The second solution is prepared by mixing TPOZ: Acetic acid: Water (1:5:4) under stirring. The two sols are then mixed and stirred for 1 h to obtain a homogenous solution. In a similar way, Mei *et al.* (2015) have prepared Si-Zr organic/inorganic hybrid sol-gel. Two separated sols, Si sol and Zr sol, are prepared. The Si sol is prepared by mixing GPTMS with ethanol and distilled water with stirring the solution. For Zr sol, TPOZ is mixed with ethyl acetoacetate, and ethanol in a volume ratio of 8:12:3

Fig. 1 Schematic presentation of preparation of Ag-doped silica-titania sol-gel material. Reproduced from Shanaghi, A., Nonahal1, H., Chu, P.K., 2017. Effects of Silica and Ag on the electrochemical behavior of titania-based nanocomposite coatings deposited on 2024 aluminum alloy by the sol-gel Method. *Journal of Alloys and Compounds* 739, 92–100.

Fig. 2 Schematic presentation of doped hybrid zirconium oxide/sol-gel coatings with thiourea and its derivatives on Al-substrate. Reproduced from Balaji, J., Sethuraman, M.G., 2016. Studies on the effects of thiourea and its derivatives doped – Hybrid/Zirconium nanocomposite based sol-gel coating for the corrosion behavior of aluminum metal. *Progress in Organic Coatings* 99, 463–473.

with stirring. Finally, Zr sol is added into the Si sol with stirring. Rodic *et al.* (2016) have also prepared organic – Inorganic hybrid sol-gel nanocoatings by combining two, alkoxide sols (Sol 1 and Sol 2), separately prepared. Sol 1 is a mixture of TEOS and 3-methacryloxypropyl trimethoxysilane (MAPTMS) hydrolyzed under acid conditions. Sol 2 is a mixture of TPOZ and methacrylic acid. Sol 1 and Sol 2 are then combined to give a final hybrid sol – Gel solution.

ZnO-doped TEOS based sol-gel material is prepared by adding ZnO nanoparticles to TEOS sol-gel (Krupa and Vimala, 2016). The latter can be prepared by mixing TEOS with ethanol, nitric acid, and water to facilitate its hydrolysis and polycondensation.

Characterization of Sol-Gel Nano-Materials

X-Rays diffraction (XRD) analysis can be used to identify the phase composition of hybrid sol-gel coatings. Rodic *et al.* (2016) have performed XRD analysis to TEOS-MAPTMS hybrid sol-gel coatings, deposited on aluminum substrate, modified with different compositions of TPOZ and methacrylic acid, hydrolyzed separately. XRD reflects the appearance of a sole peak of Al_2O_3 at all different modifying compositions due to the interaction of Al-substrate with air. No characteristic peaks are assigned for the sol-gel materials because of its amorphous nature, this limits the use of XRD analysis as a characterization technique of sol-gel materials. Characteristic peaks of ZrO_2 did not appear due to the chelation with methacrylic acid. XRD analysis of TEOS-aluminum isopropoxide based sol-gel coatings deposited on a stainless-steel substrate showed the presence of Fe, $\alpha\text{-Fe}_2\text{O}_3$ and Fe_3O_4 phases (Fig. 3(a)). In additions to these phases, SiO_2 , and Al_2O_3 phases appeared (Tiwari *et al.*, 2011). X-Rays photoelectron spectroscopy (XPS) technique has been also carried out to identify the surface composition and surface bonding based on previous XRD analysis results as shown in Fig. 3.

XPS technique has been used to analysis possible chemical states and compositions of surface elements constituting GPTMS-aluminum-tri-*sec*-butoxide based sol-gel, modified with CeO_2 nanoparticles and coated on Al-substrate (Lakshmi *et al.*, 2017). The survey spectra of coating indicate the presence of C, O, Al and Si elements. Individual binding energy scan of each element is also performed. C1s spectrum shows the presence of peaks at 283.9, 284.8, 286.2, 287.6 and 288.9 eV, corresponding to C-Si, C-C or

Fig. 3 (a) XRD and (b) XPS of TEOS-aluminum isopropoxide based sol-gel coatings deposited on a stainless-steel substrate. Reproduced from Rodic, P., Mertelj, A., Borovsak, M., *et al.*, 2016. Composition, structure and morphology of hybrid acrylate-based sol – Gel coatings containing Si and Zr composed for protective applications. *Surface and Coatings Technology* 286, 388–396.

C-H, C-O or C-OH, C=O and O-C-O, respectively. High-resolution XPS spectra of O1s show a peak at 530.6 eV assigned for the metal-O-metal bond (Ce-O/Al-O), a peak 532 eV attributed to SiO₂, and a peak at 533.5 eV corresponds to oxygen in the O-H bond, C-O-C, or C-OH groups. Si2p core level spectrum consists of a peak at 100.3 eV, attributed to Si-C bond, the main peak at about 102 eV from the Si-O-Si bonds, and a small peak at 103 eV assigned for SiO₂ network. Al2p spectrum consists of only 1 peak centered at 74.6 eV, corresponding to the Al-O bonds of Al₂O₃ and Al-O-Si bonds.

Fourier-transform infrared (FTIR) spectroscopy can be used to characterize various bonding in sol-gel materials. Balaji and Sethuraman (2017) have used FTIR to identify bonds of hybrid TEOS-GPTMS sol-gel modified with TiO₂ nanoparticles and chitosan. Fig. 4 show FTIR spectra of (a) hybrid sol-gel, (b) sol-gel/nano-TiO₂, (c) chitosan doped-sol-gel/nano-TiO₂ and (d) pure chitosan. The hybrid sol-gel coated aluminum substrate showed a band at 3417 cm⁻¹ assigned for O-H stretching. The band at 1032 cm⁻¹ attributed to Si-O-Si bond, confirming the network formation. The band at 912 cm⁻¹ corresponds to the Al-O-Si bond. Sol-gel/nano TiO₂ spectrum shows the usual bands of sol-gel and additional bands at 926 cm⁻¹ and 735 cm⁻¹, assigned for Si-O-Ti and Ti-O-Ti bonds. This suggested the formation of hybrid network containing nano-titania moieties. Additional chitosan characteristic peaks appear in other spectra, suggesting the successful doping.

Raman spectroscopy has been also carried out to ascertain FTIR results, where a strong band appears at 3022 cm⁻¹ due to O-H stretching, bands at 2924 cm⁻¹ and 814 cm⁻¹ is due to Si-O-Si bond formation and confirms the hydrolysis and condensation of sol-gel. Bands at 1109 cm⁻¹ and 920 cm⁻¹ are due to Si-O-Ti stretching vibration and the band at 814 cm⁻¹ is due to Si-O-Si bond.

The morphology of sol-gel coatings can be studied by scanning electron microscope (SEM) and for nanocoatings, transmission electron microscope is preferred. The surface morphology and energy dispersive X-Rays (EDX) analysis of TEOS-GPTMS based sol-gel/nano ZrO₂ coating has been examined, as shown in Fig. 5 (Balaji and Sethuraman, 2016). SEM photo shows the formation of uniform coating in which ZrO₂ nanoparticles are incorporated into the hybrid sol-gel matrix. The EDX spectrum of hybrid sol-gel/nano ZrO₂ showed peaks of Zr (0.15 keV, 2.02 keV, 2.12 keV), C (0.28 keV), O (0.53 keV) and Si (1.89 keV) which confirms the successful incorporation of nanoparticles into the sol-gel matrix.

Ali and Al lehaibi (2017) have performed TEM for unmodified and modified GPTMS-vinyltrimethoxysilane (VTMS) based sol-gel materials with Ti- and Al-alkoxides, shown in Fig. 6. The unmodified sol-gel has amorphous nature as shown in Fig. 5(a). Crystallinity has been enhanced upon modification and formation of hybrid sol-gel nanocomposites.

The topography and roughness of hybrid TEOS based sol-gel/Al₂O₃ nanocoating have been investigated by Atomic force microscope (AFM), shown in Fig. 7 (Tiwari et al., 2011). AFM image shows a uniform Al₂O₃ coating on sol-gel surface, small dots can be seen in agglomerates like cauliflower of about 300–350 nm diameter. A three-dimensional micrograph (Fig. 7(b)) also shows cluster of particles constituted by nanoparticles of 10–30 nm sizes.

Applications of Nano-Structured Sol-Gel Coatings

Nanosilane-based coatings are innovative coatings of interesting properties that permit its use in many industrial applications. For examples, as scratch-resistant coatings, protective coatings from corrosion, catalytic coatings, bioactive coatings for medical applications, etc. In the following section, a summary of the recent literatures focusing on sol-gel nanocoatings applications are presented in the following section.

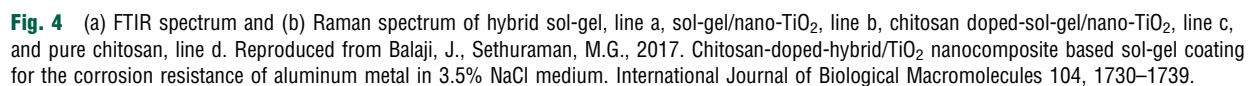

Corrosion Protective Coatings

Enhanced protection ability of GPTMS-VTMS based sol-gel coatings, for zinc corrosion in acidic media, has been presented by Ali and Al lehaibi (2017) through forming nanocomposites with Ti- and Al-alkoxides. The protection efficiency has been estimated by gravimetric, polarization, and electrochemical impedance measurements. It was found that the protection efficiency is enhanced from 69.2% to 96.2 and 95.8% for unmodified, TiO₂, and Al₂O₃/sol-gel nanocoatings, respectively. Lower concentrations of nanoparticles are favored since at high concentrations, galvanic corrosion between nanoparticles and zinc substrate is possible.

A conversion coating is applied on mild steel prior to sol-gel/Al₂O₃ nanocoating to improve the corrosion resistance of mild steel (Tiwari et al., 2011). Fig. 8 shows a comparison between polarization curves of conversion coated and conversion followed by sol-gel/nano-Al₂O₃ coated mild steel in 3.5 wt% NaCl solution. Mild steel coated with the conversion layer showed high corrosion resistance and showed barrier type protection up to ~1.0 V. This is further reduced by ~3 orders of magnitude on subsequent sol-gel/Al₂O₃ nanocoating.

Chitosan doped TEOS-GPTMS hybrid sol-gel/TiO₂ nanocoating is applied successively for corrosion protection of Al-substrate in 3.5% NaCl solution (Balaji and Sethuraman, 2017). Impedance results show that charge-transfer resistance values increased in the order Chitosan doped sol-gel/TiO₂ > sol-gel/TiO₂ > sol-gel > bare Al-substrate, with corresponding coatings protection efficiency values of 94.1, 90.6 and 74.8%, as shown in Fig. 9. The electron-rich oxygen atom attracts the hydrogen in the chitosan leading to the formation of a densely packed adhesive sol-gel coating over Al-substrate.

Silica nanoparticles have been incorporated into TEOS-GPTMS based sol-gel to enhance the corrosion protection ability for mild steel substrate (Mora et al., 2017). Introducing of silica nanoparticles improve the barrier properties of the coating due to cracking prevention and reduced porosity. Further improvement of the corrosion protection is observed by incorporation of functionalized silica nanoparticles compared to unfunctionalized ones. This is possibly due to a dispersion improvement and a stronger interface between the matrix and nanoparticles. Fig. 10 shows the time dependence of the pore resistance for unmodified sol-gel, modified sol-gel with unfunctionalized, and functionalized with silica nanoparticles. The coating with functionalised silica nanoparticles has the highest pore resistance, reflecting the most effective barrier properties of the coating.

of low wettability enables to use the hybrid sol-gel/nano-ZrO₂ coating for corrosion protection. Upon coating, the polarization resistance increased up to four orders of magnitude, compared to bare Al-substrate.

Other Applications

Nano-ZrO₂/TEOS based sol-gel combined with chlorotrifluoroethylene-vinyl ether copolymer results in hard, scratch-resistant and transparent coating (Suriano *et al.*, 2017). Durability of the hybrid coating is assessed by water contact angle measurements, pencil and AFM scratch hardness and adhesion tests. Pencil hardness tests confirm the scratch resistance and durability of the hybrid coatings at the macro-scale. AFM indentation and nano scratch tests are used to evaluate the elastic modulus and the dynamic hardness of the hybrid systems, resulting in a high modulus (up to 31 GPa) and high-level scratch hardness (up to 2 GPa). The hybrid coatings exhibit a superior long-term stability and show excellent mechanical strength, high level of hardness and superior integrity after long-term light exposure at low and intermediate zirconia-to-silica ratio. The excellent scratch resistant properties of the hybrid coating permit its applications in automotive field, consumer goods, photovoltaic and optical devices. Nano-fluorinated silica and epoxy composite coating is successfully constructed by the coaxial electrospinning method, as showing in Fig. 11 (Li *et al.*, 2018). Fluorinated nano-silica with uniform nano-size is distributed evenly on the micro epoxy particles, showing a

special micro-nano hierarchical structure. Contact angles measurements in water and ethanediol reached $165 \pm 3^\circ$ and $152 \pm 3^\circ$, respectively, showing a superamphiphobic and good anti-sticking status. Evident reinforcement effect showed improved modulus and hardness in the nano-indentation test. In addition, durability of the superamphiphobic coating was assessed by performing harsh chemical environments immersion and scotch tape test, where the prepared coating can resist damage from strong polar organic solvent and repeated sticky, which can broaden the fields of application.

Conclusion

- Nano-structured sol-gel materials, containing nanoparticles or nanomoieties, can be prepared either by simultaneous hydrolysis and condensation of both Si and metal precursors, or by successive and consecutive synthesis steps.
- XRD structural characterization of sol-gel nanomaterials indicates the amorphous nature of these materials, only characteristic peaks for the nano-oxide appears. The formation of a hybrid network containing nano-metallic moieties is indicated by the appearance of M-O-Si band in FTIR spectra. TEM images show that the crystallinity of sol-gel materials can enhanced upon modification with nanoparticles or nanomoieties.
- Nano-structured sol-gel coatings is applicable to corrosion protective coatings for many metals in different media since nanoparticles improve the barrier properties of the coating due to cracking prevention and reduced porosity and increased hydrophobicity. Lower concentrations of nanoparticles are favored since at high concentrations, galvanic corrosion between nanoparticles and metal substrate is possible.

Introduction

The newly developed “instant” coffee capsules machines are progressively imposing on the market, replacing traditional brewing equipments worldwide. Instant coffee machines are fully electric and designed to brew coffee, in both domestic and working environments, with short brewing time, safely and silently. A large variety of coffee blends and other brews can be brewed, thus satisfying a broad range of dissimilar needs of the customers. Nevertheless, “instant” coffee machines rely on plastic or aluminum capsules. Coffee capsules, more than any other consumer items, have negative environmental and social effects. An estimated 10 billion coffee capsules were manufactured each year, producing an astonishing amount of 120,000 tons of plastic waste worldwide to be disposed of 70,000 tons are generated in Europe alone, with the capsules not being recyclable in municipal facilities because they often combine multiple materials ([EU LIFE Project](#)). The coffee capsules are essentially fabricated joining two or more conventional materials like Polyethylene (PE), Aluminum, Ethyl Vinyl Alcohol (EVOH), and Polyethylene Terephthalate (PET). That gives rise to severe environmental concerns: (i) PET and PE are oil-based polymers and their manufacturing process involves about 15,000 tons of non-renewable resource; (ii) PE, PET and aluminum downstream manufacturing represents a significant source of CO₂ emission (i.e., more than 410,000 tons). A potential solution to face the environmental issues related to the manufacturing and landfilling of the coffee capsules lies in the employment of the so-called bio-based materials. Bio-based materials only rely on biological matter. At present, the recourse to fully bio-based materials, certificated compostable or, at least, biodegradable, in the fabrication of coffee capsules and, in general, in food & drug packaging and containers is limited by their often mediocre mechanical, physical and chemical performance. Bio-based materials do not feature satisfactory mechanical strength (above all, toughness and impact resistance), sufficient thermal stability (at 95–97°C for 20 s) and reduced permeability as dictated by the stringent customer requirements (i.e., reduced transmission rate of oxygen and moisture to protect coffee). In contrast, the successful industrialization of fully bio-based, compostable or biodegradable, materials that comply with the strictest technological demands posed by the packaging market, would allow the attainment of impressive environmental benefits: (i) saving 70,000 tons of waste from landfills or incinerators in Europe, assuring biodegradability of the product at end-of-life for billions of coffee capsules; (ii) saving 15,000 tons of oil involved in the current coffee capsules manufacturing process, meaning 100% reduction of the employment of fossil feedstock; saving 405,000 tons of CO₂ equivalent ascribed to PE, PET and aluminum manufacturing process; (iii) saving 20,000 tons of bauxite and others dangerous pollutants involved in aluminum manufacturing process ([EU LIFE Project](#)). The environmental benefits of high performance bio-based materials will be even greater, if the whole European plastic market would be taken into consideration. In fact, 25 million tons of plastic materials are not recyclable today and the introduction on the market of biodegradable/compostable materials could reduce significantly the amount of plastics to landfill each year. This would also lead to an additional saving of 100 Mt of oil that, each year, is employed for the manufacturing of conventional plastics and, in turn, a reduction of 35,000 Mt of CO₂ equivalent emitted in PE and PET manufacturing process.

The methodological approach herein described, was designed to overcome limitations of bioplastic materials during melt processing. Specifically, this work aims at the enhancement of thermal and mechanical properties of PLA based materials, processed by injection molding.

State of Art of the Use of PLA in the Market of Coffee Capsules

The market of coffee capsules is quickly increasing in size and is highly dynamic, with a large number of different technological solutions available. After being used, coffee capsules cannot be easily recycled, as they need to be cleaned from the exhausted coffee before starting any recovery step. They can not be dismissed in the compost, as the plastics, which are commonly used to fabricate them, do not degrade. The introduction of compostable materials in the manufacturing of compostable coffee capsules would allow their simple disposal in the compostable fraction together with the exhausted coffee inside. Yet, the coffee capsules are used in “instant” coffee brewing equipment. They must ensure satisfactory thermal and mechanical properties: (i) compostable according to EU Industrial composability regulations according to the regulation EN13432; (ii) no recourse to nano-materials that can be dangerous for health and environment (no working regulations in EU27); (iii) suitable for food contact according to the Regulation of the European Commission No. 10/2011 on food contact plastic materials and/or safe for humans and environments according to REACH Regulation No 1907/2006 of the European Parliament; (iv) easy to process polymer (extrusion; injection, compression and stretch blow molding; sheet polymer forming; thermoforming; fibres, foams, etc.); (v) tough and thermally stable (min. 100°C for 20 s); (vi) elastic modulus (~4.0 GPa, typical value for as-is PLA-based materials); elongation at break (>> 5.0 %, typical value for as-is PLA-based materials).

In this respect, as it is (neat) PLA resin features appreciable elastic modulus and tensile strength, not far from petroleum-based polymers. Nonetheless, PLA resin is usually brittle, featuring limited thermal resistance, toughness and resiliency. Typical approaches to overcome the drawbacks of the neat PLA resin involve the compounding of PLA by the incorporation of additional materials, like other resins (blending process), mineral fillers and a large variety of additives (nucleating agents, filler dispersants, bonding agents, impact modifiers, lubricants, melt strength enhancers, etc.) (Yu *et al.*, 2006). One of the most common approaches to increase the performance of PLAs is to introduce nano-fillers, including layered silicates, carbon nanotubes, hydroxyapatite, layered titanate, aluminum hydroxide, etc., inside the resin to achieve higher performance. The debate on PLA nano-composites as regards to the safety of nano-materials is ongoing in the scientific community, especially when the final materials are involved in direct food contact. Nano-fillers could migrate inside the food and, if ingested, they could be significantly dangerous for human health. Other routes are, however, promising to improve the properties of PLA polymers. In particular, the properties of PLA can be enhanced by a number of combined actions, which might concur to the establishment of the desired final properties (for example, high thermal stability, good toughness, high dimensional accuracy and stability, etc.). Fine-tuning of morphological structure in the polymers, especially of the crystalline phase can concur to the design of high performance PLA materials, which can comply with the stringent specifications driven from the coffee market. Crystallization of PLA can be achieved by the addition of nucleating agents and careful control of the temperature variations during melt processing. Lastly, reinforcement of the organic matrix with high compatible micro-sized fillers with specific surfaces, establishment of chemical bonding between fillers and matrix in the compounds by organo-silanes, blending with low amount of performant polymers and proper usage of additives can increase further the final properties of the material.

In this respect, many efforts have been made in the past years by Academia to analyze the effect of compounding PLA with other materials. Mathew *et al.* (2005) investigated the mechanical properties of PLA composites containing microcrystalline cellulose, wood flour and wood pulp. Oksman *et al.* (2003) reported that the tensile strength for PLA-flax fibre composites is about 50% better than PP-flax composites, which are used today in many automotive panels. Huda *et al.* (2006) evaluated the mechanical and physical properties of PLA composites containing chopped glass fibre or recycled newspaper cellulose fibre. The study showed that both mechanical and physical properties of the recycled newspaper composite compared favourably with glass fibre reinforced PLA composite, suggesting that these cellulose fibre reinforced composites have the potential to replace glass composites in applications where very high load bearing capabilities are not needed. Shibata *et al.* (2003) evaluated the effect of dispersing abaca fibre (Manila hemp) in several biodegradable polyesters, including PLA. These authors observed a C-mold could increase flexural moduli for poly(butylene succinate) and polycarbonate/PLA blends as the fibre content increased. In contrast, for the PLA-abaca fibre composite, a minimal increase in flexural strength was observed, which is attributed to inherent high flexural strength of neat PLA.

Despite all the research performed up-to now in Academia, a satisfactory PLA-based formulation that can be used in highly demanding applications, such as the fabrication of coffee capsules (but also in many others consumers goods), has not yet been proposed for the market. More recently, Russo *et al.* (2014) investigated the reinforcement of PLA polymers by dispersing micro-talc in the organic matrix, which was found to be extremely beneficial to the final properties of the compound. Barletta *et al.* (2014b) also showed the effect of bonding organo-silane molecules to improve the overall mechanical behavior of organic resins when deposited on inorganic and organic substrates in the form of surface overlaying coatings (Barletta *et al.*, 2014a,b). During some preliminary trials, they showed the satisfactory results achievable, combining the good performance obtainable using talc fillers and organo-silane intermediates to favor bonds among organic and inorganic materials. In particular, they found that pre-treating micro-lamellar talc produced by mechanical exfoliation with 3-aminopropyltriethoxysilane and dispersing it in a neat PLA resin could determine, during lab-scale experiments, an astonishing improvement in the thermal stability and mechanical response of the resulting materials, opening up the route to exploit the PLA in many applications for consumer goods. Adding nucleating agents, impact modifiers and plasticizers to PLA-based materials reinforced with micro-lamellar talc, pre-treated by 3-aminopropyltriethoxysilane, were found to allow the achievement of high performance compounds, potentially suitable for the injection molding process of complex shaped items.

Scope of the Work

In spite of the significant advances in the engineering of PLA-based plastics, bio-derived and biodegradable aliphatic polyesters still suffer from severe hydrolytic degradation mechanisms when melt processed (especially, injection molded) at high temperature and in the presence of oxygen and environmental moisture. During injection molding, the overall performance of the molded items is strictly dependent on the residence time of the bioplastics in the barrel and in the mold. Longer residence time triggers significant degradation mechanisms of the resin that can compromise the final performance of the molded items. Preventing or limiting the onset of the thermal degradation of custom-built Poly Lactic Acid (PLA) formulations during injection molding together with the appropriate strategy to engineer the PLA formulations is therefore the purpose of the present work. In this framework, bioplastics were formulated by reactive compounding extrusion of PLA, PBS, talc, compatibilizing agents and processing additives. The resulting compounds were injection molded to get two kinds of components, flat slabs and cups. Thermo-mechanical performance was evaluated by both static, impact and fracture tests. The results showed that combining wise design of the material formulation and optimizing operational parameters during injection molding can lead to significant progress in the performance of the molded items, opening up great market opportunity for PLA-based materials.

Engineering of the PLA Formulations

The polymers of lactic acid are broadly available on the market, with different molecular weights and D-Isomer content. In the present work, a commercial grade, 3260 HP (Nature Works, Minnetonka, Minnesota) is investigated and a proprietary formulation developed. The 3260 HP grade is characterized by a low content of the D-Isomer and low molecular weight. The low level of the D-Isomer in the polymer allows the following advantages: (i) faster quiescent crystallization speeds (i.e., slower cycle times); (ii) higher levels of crystallinity; (iii) higher stiffness above glass transition temperature; (iv) higher crystalline melting temperatures; (v) higher degrees of stress-induced crystallization at lower strain (or higher temperatures). While the molecular weight of the starting polymeric chain is, instead, important for the final mechanical properties of the material, the choice of a low molecular weight is beneficial for the crystallization speed. A PLA grade with low molecular weight means dealing with chains of enhanced mobility. Higher mobility means better attitude of the polymeric chains to dispose themselves according to tidy orders in the material, thus promoting higher degree of crystallinity quickly. Crystallinity is pivotal in the achievement of high thermal stability. Micro-lamellar talc was chosen as nucleating agent for the 3260 HP PLA-grade. It is small (5–10 microns) but not nano-sized, therefore, suitable for direct food contact. Talc distribution and dispersion inside the PLA matrix was initially achieved by extrusion compounding with a twin-screw co-rotating extruder (Haake PolyLab PW24, Haake, Karlsruhe, Germany), setting the appropriate and proprietary chewing profiles on the screws with a mid-barrel temperature of $\sim 180^{\circ}\text{C}$.

Fig. 1 shows the difference between PLA pellets before and after the addition of the nucleating agent (i.e., micro-lamellar talc produced by mechanical exfoliation and treated with 3-aminopropyltriethoxysilane). When the pre-treated talc is dispersed appropriately inside the material by co-rotating twin-screw extrusion and the appropriate chewing profile of the screws, it favours the crystallization process of the low D-Isomer, low molecular weight PLA grade. The secondary effect of the crystallization is a loss of transparency of the polymer.

Figs. 2 and 3 show the performance of the PLA alone and of the PLA after extrusion compounding with talc as nucleating agent. Both figures report the elastic modulus, mechanical strength, toughness, ductility, impact resistance, heat deflection temperature that were measured during preliminary tests on injection molded flat slabs.

Fig. 2 focuses on the magnitude of the thermo-mechanical properties measured. **Fig. 3** compares them on a normalized 0–100 scale. The flat samples were injection molded (S-2000i/50B, Fanuc LTD, Oshino-mura, Yamanashi, Japan) at a mid-barrel temperature of $\sim 205^{\circ}\text{C}$ in a multi-purpose molds, designed according to the current regulations for each test with a proprietary temperature of the mold walls. The talc as nucleating agent was found to modify significantly the response of the commercial grade PLA. After the addition of the talc, all the vertices of the radar plot (**Fig. 3**) expanded significantly. The mechanical strength of the material increased as well as its toughness, impact resistance and, especially, thermal stability (i.e., heat deflection temperature) that has, surprisingly, doubled. However, this is not uncommon in PLA-based materials. [Wootthikanokkhan et al. \(2013\)](#) reported heat deflection temperature (HDT) of above 120°C for 20 ppf kenaf fibre – PLA composite. Before the addition of the nucleating agent (talc), the thermal stability of the material relied on its amorphous phase only and, thus, on the glass transition temperature of the commercial grade PLA, that is very low (around 52°C). After the addition of the modified nucleating agent (talc), the thermal stability of the material depended on the large crystalline phase formed in it. That allowed the material to be stable well over the temperature of 100°C , as required by the industrial requirements for the plastic coffee capsules. **Fig. 4** reports the improvement in the thermal stability of the commercial PLA grade (3260 HP) after the addition of the talc pre-treated with 3-aminopropyltriethoxysilane and achievement of a sufficient degree of crystallization. After talc addition, the molded items remain flat even after dipping in hot oil at 150°C . The untreated PLA deforms, with a significant warpage of the edges of the molded items.

Despite the improvement in the general mechanical properties of the material observed in **Figs. 2 and 3**, some preliminary tests by injection molding of the coffee capsules with the same material formulation showed that the resulting capsules were still very

Fig. 1 The pellet achieved by extruding the commercial grade PLA (3260 HP) without nucleating agent (a) and with nucleating agent (b).

Fig. 2 Summary of the properties (PLA grade 3260 HP and PLA grade 3260 HP + talc).

Fig. 3 Radar plot that compares the most important properties of the commercial grade PLA after injection molding in flat samples and the same grade of PLA after compounding with talc and injection molding in flat samples.

brittle, even after the application of very low pressure (Fig. 5). To improve the performance of the molded capsules, distribution and dispersion of the talc pre-treated with 3-aminopropyltriethoxysilane inside the PLA matrix were investigated. Talc is hydrophilic, while PLA is essentially hydrophobic. To compatibilize talc and PLA and improve homogeneity, a custom compatibilizer was introduced. The typical compatibilizers available in the market are acrylate polymers. They are effective to compatibilize talc and PLA, but not compostable as often reported in the literature (Cardoso Arruda *et al.*, 2015).

The compatibilizers herein studied is instead based on a PLA backbone, with both maleate or glycidyl(methacrylate) (i.e., epoxy) reactive groups. The commercial name of compatibilizer involving maleic anhydride (MAH) grafted PLA (PLA-MA) is Scona TPPL 1112 PA(BYK Additives & Instruments, Altana AG, Wesel, Germany), the one involving glycidyl methacrylate (GMA)

Fig. 4 Different thermal stability of the PLA dipped in hot oil up to 150° before dipping (a, b) and after dipping (c, d) according to the degree of crystallinity: (a, c) low crystallinity; (b, d) high crystallinity.

Fig. 5 Brittleness of a coffee capsules manufactured by the addition of talc in the commercial grade of PLA (3260 HP) through an injection molding pilot plant.

grafted PLA (PLA-GMA) is named Scona TPPL 1214 PA, (BYK Additives & Instruments, Altana AG, Wesel, Germany). They are both compostable and food safe.

The structure of the maleate reactive group is presented in Fig. 6. The compatibilizing agents can be effective to bridge the talc to the PLA promoting the formation of covalent bonds or of simpler physical interactions between the hydroxyl groups on talc and the maleate or epoxy group of the compatibilizers.

The mechanisms are therefore very similar to the ones depicted in (Liu and Zhang, 2011) for conventional acrylate-based compatibilizers. The PLA-based compatibilizing agents were found extremely effective in promoting the distribution and dispersion of the hydrophilic talc pre-treated with 3-aminopropyltriethoxysilane in the largely hydrophobic PLA matrix, improving the overall behavior of the resulting materials. The compatibilizing agents was also extremely effective to promote the chain extension of the commercial grade PLA (NatureWorks LCC, 3260 HP), raising efficiently the average molecular weight of the PLA and preventing the possible negative effects of the hydrolytic degradation of the PLA during the following melt processing. Fig. 7 summarizes the mechanisms of the compatibilizing agents developed and the related chemical reaction routes. Fig. 8 depicts the mechanisms of the chain extensions on PLA. In particular, the compatibilization is achieved by exploiting the reactivity of the terminal hydroxyl groups of the PLA chain that can combine with the functional groups of both the compatibilizing agents.

Figs. 9 and 10 show the performance of the PLA compounds after the addition of the compatibilizing agents, with significant improvements achieved in terms of all the properties under investigation, especially of the heat deflection temperature that can benefit of the better dispersion of the talc up to reach an astonishing 145°C. The talc can act as nucleating agent and promote crystallization of the polymeric chains more effectively. Despite the improvements of the materials, the injection molding tests were not satisfactory yet, as the resulting coffee capsules were still affected by significant brittleness (see the injection-molded capsule shown in Fig. 5). Use of plasticizers or of alternative solutions to improve the toughness and impact resistance of the material was, therefore, studied. In particular, the involvement of a polymer with low glass transition temperature was investigated. This approach is becoming very common in the scientific literature (Liu and Zhang, 2011) and in the technical practice, contrary to the approach that makes use of conventional plasticizers such as phthalates, epoxidized soybean oils or esters citrates (Thummarungsan *et al.*, 2016; Chieng *et al.*, 2014; Harte *et al.*, 2013). The polymers with low glass transition temperature are

intended to replace conventional plasticizers in the PLA formulation, creating a so-called secondary polymeric phase in the PLA matrix and exploit its high flexibility already at room temperature. PBS (Bionolle 1020 MD, Showa Denko K.K., Tokyo, Japan) was chosen as material for the formation of the secondary polymeric phase in the PLA compound.

Figs. 11 and **12** show the compatibilization mechanisms to recombine the PLA with the possibly incompatible PBS. Once again, the reactivity of the hydroxyl functionalities of both PBS and PLA were used for compatibilization purposes, using the same compatibilizing agents based on maleate and glycidyl methacrylate groups. PBS and PLA are basically immiscible polymers (Hu *et al.*, 2018), with PBS forming small “droplets” (domains) inside the PLA matrix. Compatibilization means in this case good dispersion and distribution of the PBS domains inside the PLA, with micro-domains homogeneously dispersed and distributed all over the PLA matrix.

Fig. 11 Compatibilization mechanisms of the PLA with the PBS: the reaction scheme with maleate groups.

Fig. 13 shows the pellets that were produced by the addition of PBS inside the PLA matrix. After the addition of PBS, the materials showed a significant improvement in the global mechanical, physical and chemical performance as evidenced by the radar plot and bar chart of **Figs. 15** and **16**.

Fig. 14 shows that PBS acts as secondary polymeric phase by dispersing and distributing uniformly inside the PLA matrix in the form of small droplets. The good dispersion and distribution of the PBS in the PLA ensure the improvement of the material properties. Specifically, the molded substrates after the dispersion of PBS inside the PLA were found to feature good toughness and strength. Also, the thermal stability of the slabs was extremely good, with peak temperature well over 140°C, specifically 144°C, under a pressure of 5 Mpa (**Fig. 15**).

Figs. 15 and **16** summarize the achieved properties by testing the flat slabs according to the international regulations. Melt blending of PLA with PBS improved toughness, impact resistance and ductility. These materials were then processed by injection molding (process parameters not disclosed) to test them for the manufacturing of coffee capsules. The resulting capsules were ultimately strong and flexible enough for practical purposes.

The capsules also complied with the requirements imposed by the market of brewing equipments. **Fig. 17** shows the capsule manufactured with the compound of PLA, PBS and additives as described before. The whitish color of the capsules symbols the good crystallinity achieved during the injection molding. Similarly, the geometrical details of the capsules were reproduced with great accuracy, leading to a final product of utmost quality.

Injection Molding of Coffee Capsules

Despite the advance in engineering of PLA, injection molding of the capsules is still a troublesome process. The process must be quick to reduce the final cost of the coffee capsules. A whole molding cycle should last not more than 3 or 4 s to be competitive. In addition, the wall temperature of the mold should be very high (> 100°C) to promote a quick crystallization of the PLA in-mold and without any further post-annealing that could increase the overall cost of the process. Nevertheless, if the wall temperature is increased at 100°C, the ejection process of the part from the mold can be troublesome. The PLA blend becomes soft and sticky and ejection could be not correct. **Fig. 18** shows some results about the ejection of the capsules from the mold, varying the wall temperature, with the critical range emphasized. Metal release agents can be, however, added to the compound to improve part ejection even at high wall temperature. A small jet of compressed air in the male mold, right in the middle of the capsule "head"

Fig. 12 Compatibilization mechanisms of the PLA with the PBS: the reaction scheme with glycidyl methacrylate groups.

Fig. 13 Pellets produced by blending of PBS and PLA and injection molding of flat samples (a) PLA grade 3260 HP; (b) PLA grade 3260 + talc; (c) PLA grade 3260 HP + talc + compatibilizer; (d) PLA grade 3260 HP + talc + compatibilizer + PBS.

Fig. 14 SEM images show the morphology of talc in the PLA matrix, the distribution of PBS inside the PLA matrix (see the spherical voids that corresponds to the presence of PBS “droplets” before their removal by enzymatic attack with proteinase-k) and the crystalline structure of the polymeric matrix in four test-cases: (a) 2 wt% talc; (b) 5 wt% talc; (c) 15 wt% talc; (d) 30 wt% talc.

Fig. 15 Overall properties of the injection molded samples achieved by blending PLA and PBS, as copolymer.

can simplify and speed up significantly the extraction of the coffee capsules from the mold. It can, however, have a negative effect on material crystallization as it can promote a faster cooling of the polymer and the resulting block of the crystallization process.

The last issue concerns the hydrolytic degradation of the material when melted inside the chamber. The permanence time of the material in the chamber depends mostly on the ratio between the volume of the chamber of the injection molding equipment (i.e., the melting chamber) and the volume of the cavity inside the mold. In the prototypal equipment used for the preliminary molding tests, the ratio is 80:1. This means that about 80 capsules can be produced by the material contained inside a single spatial volume of the melting chamber. If the cycle time to produce a single capsule is 3 s, the overall maximum residence time of the molten material in the chamber can be 240 s, with an average permanence time of the material of 120 s. If the cycle time increases at 8 s, as sometimes can happen, the overall maximum permanence time of the material inside the chamber is an unacceptable 640 s. This time is extremely long and can bring to severe hydrolytic degradation of the PLA compound. Such

Fig. 16 Radar plot of the injection molded samples achieved by blending PLA and PBS, as copolymer.

Fig. 17 Coffee capsule that was injection molded using a compound of PLA (grade 3260 HP) and PBS (as secondary phase).

Fig. 18 Part ejection and wall temperature of the mold.

parameter is therefore of great importance in the manufacturing of the industrial devices. This should feature a small chamber to minimize the residence time of the material at high temperature during the injection molding process. Multi-cavity molds simplify significantly this task, reducing the permanence time of the material in the melting chamber of the injection molding equipment, as the molten material can be injected in more cavities of the same mold.

Conclusions

This work presented the results obtained by applying a methodological approach to overcome limitations of bioplastic materials in melt processing applications. The method involves a strategy for the formulation of the compound, in particular the combined effect of a mineral filler, compatibilizers and a copolymer was subsequently evaluated. The components have been compounded by reactive extrusion, which allowed a homogeneous dispersions and distribution of additives as shown by SEM images.

Based on the experimental evidences, the following conclusions can be drawn:

- (1) Addition of talc inside the polymeric blends allows to customize the degree of crystallinity of the materials and, in turn, potentiate the thermal stability of the resulting material;
- (2) Addition of the chain extenders allow to increase the compatibilization between the different polymeric phases, the talc and the polymeric blends as well to compensate the decrease in the molecular weight of the polymer following the thermal processing;
- (3) Addition of the PBS allows to increase toughness of the polymeric blends by the onset of a ductile secondary polymeric phase inside the primary phase based on PLA;
- (4) Injection molding with low cycle time and high wall temperature allow to preserve the features of the polymeric materials, optimizing the crystallization degree and minimizing the occurrence of the thermal degradation.

PLA/PBS blends engineered with talc and chain extenders are extremely promising to manufacture plastic compounds suitable for the fabrication of coffee capsules that are compostable and relying, almost completely, on renewable resources. Furthermore, the proposed methodological approach can be applied in different market segments, allowing to support scientists and practitioners in developing innovative solutions to face the everyday environmental challenges in the field of food packaging.

Introduction

To improve the performance of adsorption cooling/heating systems, it is urgent to find new adsorbent with excellent thermophysical properties compared to commercial adsorbents. Higher adsorption capacity and faster kinetics are the keys to develop adsorbent materials. Several adsorbents were studied so far for ethanol and CO₂ adsorption, the promising two refrigerants in heat pump applications. Among them, metal-organic frameworks (MOFs), potassium hydroxide (KOH) activated phenol resin, zeolite and silica gel were extensively investigated (Younes *et al.*, 2017). Considering the ethanol adsorption capacity, KOH treated phenol resin showed maximum capacity (1.98 kg kg⁻¹) followed by MOFs (1.1 kg kg⁻¹), and activated carbon fiber (0.8 kg kg⁻¹). For CO₂ capture, storage and utilization in engineering applications, activated carbons (Fan *et al.*, 2016; Jribi *et al.*, 2017), zeolites (Abdul Kareem *et al.*, 2018), functionalized porous silica gels (Aboudi and Vafaezadeh, 2015), metal-organic frameworks (Fu *et al.*, 2017; Qasem *et al.*, 2017) and covalent organic frameworks (Olajire, 2017) were studied. Among studied adsorbents, activated carbons (ACs) are found very promising due to its attractive surface properties, internal pore structures, low cost and possibility of being produced from renewable biomass precursors (Danish and Ahmad, 2018). Saha *et al.* (2011) reported the maximum CO₂ adsorption capacity onto activated carbon fiber and powder were 1.0 and 1.7 g g⁻¹, respectively. Biloé *et al.* (2002) and Himeno *et al.* (2005) measured equilibrium CO₂ adsorption capacity onto several activated carbons and showed the maximum CO₂ uptake onto Maxsorb was 1.1 cm³ g⁻¹. The maximum CO₂ adsorption capacity for MOF-177 was found 1.47 g g⁻¹ at ambient temperature and 3.5 MPa pressure (Millward and Yaghi, 2005). Fan *et al.* (2016) studied the adsorption cooling cycle using activated carbon/CO₂ pair and achieved the best cooling performance for the pore widths ranging from 7 to 15 Å with higher limiting uptakes or pore volumes.

Literature review indicates that activated carbons are superior adsorbent compared to others in terms of adsorption capacity of ethanol and CO₂. However, still adsorption uptakes of those refrigerants are not in the satisfactory level for wide spread commercialization of the systems. Moreover, the extensive use of ACs is limited due to the production cost and scarcity of good quality precursor materials. Therefore, abundantly available and renewable precursor material can be a good choice for producing high quality ACs. For this purpose, ACs are synthesized from two waste biomass precursors, namely waste palm trunk (WPT) and mangrove (M). The details synthesis procedure including surface morphology and elemental composition are presented in the previous article. This article investigated the porous properties, thermal conductivity, and adsorption characteristics of ethanol and CO₂ onto newly synthesized biomass-derived ACs. Some significant contributions in this article are:

- N₂ adsorption at 77K is measured for estimating surface area, pore volume and pore size distribution.
- Alpha-s (α_s) and non-local density functional theory (NLDFT) are employed to calculate the specific surface area, pore volume, average pore width, and pore size distribution.
- Estimated porous properties are then compared with widely used adsorbents.
- The thermal conductivity of the synthesized ACs is measured.
- Effect of activation conditions on porous properties and thermal conductivity are investigated.
- Equilibrium adsorption performance of ethanol and CO₂ onto synthesized ACs is presented for a wide range of adsorption temperatures and pressures.

Experimental Details

Materials Formulation

The abundantly available and renewable precursor materials, namely waste palm trunk (WPT) and mangrove (M) are employed for synthesizing high grade ACs that can be used in various applications including adsorption heat pump (AHP) systems and CO₂

capture or storage. The properties of raw material, detailed synthesis procedure of ACs, and few fundamental properties of synthesized ACs such as yield, surface morphology, and elemental composition analysis are presented in the previous article entitled as "Synthesis of high grade activated carbons from waste biomass" written by the same authors. Total twelve AC samples (six from each biomass precursor) are synthesized by changing the carbonization and activation conditions. **Table 1** represents the AC samples prepared from WPT and M with sample naming code used in subsequent sections.

Methodology for Thermophysical Properties

N₂ adsorption/desorption isotherms are measured at 77K using volumetric adsorption equipment (Belsorp-Max-S) supplied by BEL Japan Inc., Japan. Before the N₂ adsorption measurement, sample is degassed under vacuum condition at 120°C for several hours for removing unwanted gas and moisture adsorbed on the surface. The sample mass is correctly measured after degassing and around 60 mg mass of each sample is used for this experiment. After that, sample tube is connected to system and performed the leakage test. The system executes the whole experiment automatically by the instruction given in software.

Thermal conductivity measurements are conducted employing C-Therm TCi thermal conductivity analyzer provided by C-Therm Technologies Ltd., Canada. The schematic diagram and experimental details can be found elsewhere (Pal *et al.*, 2017c). Thermal conductivity measurement of all WPT and M-derived AC samples is performed at ambient temperature and pressure conditions. The TCi system employs the modified transient plane source (MTPS) technique for thermal conductivity measurement. The major components of this instrument are (i) one-sided interfacial heat reflectance sensor, (ii) controller unit and (iii) data processing software. The sensor has a central spiral shape heater surrounded by a guard ring. A known constant current is applied to the sensor's spiral heating element which generates a small amount of heat to provide the sample. Approximating a one-dimensional heat flows from the sensor into the tested sample. During the measurement, the sample is heated by approximately 1–3°C. Depending on its thermal properties, the sample absorbs some portion of the heat and the remaining heat causes a temperature rise at the sensor-sample interface. Temperature rise causes the voltage drop on the spiral heated which is measured by the system before and during the measurement. The voltage data are then converted to thermal conductivity value by the data processing software. The temperature increasing rate at the sensor-sample interface is inversely proportional to the thermal conductivity value of the tested sample (Pal *et al.*, 2017c).

Methodology for Adsorption Uptake Measurement

The magnetic suspension adsorption measurement unit of type MSB-VG-S2 for low pressure ethanol vapor adsorption and MSB-GS-100-10M for high pressure CO₂ gas adsorption are employed to measure adsorption capacity for both type of synthesized samples. Both experimental set up are supplied by MicrotracBEL, Japan. **Figs. 1** and **2** show the schematic diagram of ethanol and CO₂ adsorption uptake measurement units, respectively. The adsorption measurement principle for both the instruments is almost similar. However, depending on the measurement pressure, two systems use different types of pressure sensors and the configuration. For low-pressure uptake measurement, three types of absolute pressure gauges (1) 3500 kPa, Keller PAA-35XHTT-35; (2) 133.3 kPa, MKS 628B13TBE1B; and (3) 1.33 kPa, MKS 628B12TBE1B are used in series to measure the ethanol vapor pressure with an accuracy of 0.15%–0.25% of full scale. The temperature of liquid ethanol is measured and maintained precisely by platinum resistance temperature element (100 Ω). However, for

high-pressure measurement, one absolute pressure gauge 10,000 kPa, Keller PAA-35X is used to measure the pressure of CO₂ gas with an uncertainty of ± 0.1 of full scale. Excluding the pressure and temperature sensors, the other similar components of both instruments are magnetic suspension balance unit; isothermal circulation oil baths to maintain adsorber and evaporator temperatures; isothermal air bath to avoid condensation through connecting tubes; a series of vacuum pumps including diaphragm, rotary, and turbo-molecular types. Both the system employs nitrogen gas to operate the valves whilst pressurized helium gas is used for checking the leakage as well as to compute the void volume and buoyancy effect. During adsorption measurement, the buoyancy effect is considered automatically by the system. The main feature for both the instruments is that it measures the adsorption amount directly by the magnetic suspension balance unit. The resolution of magnetic suspension balance is $\pm 10 \mu\text{g}$ to record the sample mass. The weight measurement repeatability of the magnetic balance is $\pm 30 \mu\text{g}$ with relative error $\pm 0.002\%$ of the reading.

Fig. 3 N_2 adsorption/desorption isotherms of WPT-derived ACs at 77K.

Fig. 4 N_2 adsorption/desorption isotherms of M-derived ACs at 77K.

Porous Properties of Biomass-Derived ACs

Nitrogen (N_2) adsorption is one of the standard procedures to analyze the porous properties of various adsorbent materials, which includes the surface area, pore volume, and pore size. N_2 adsorption/desorption isotherms of WPT and M-derived ACs are shown in Figs. 3 and 4, respectively. A sharp increase in the N_2 adsorption amount at very low relative pressure ($P/P_0 \leq 0.01$) is a characteristic feature of microporous materials, which is observed for all the synthesized AC samples. From the N_2 adsorption and desorption isotherms, it can be seen that biomass-derived ACs possess not only micropores but also some fractions of mesopores. In addition, there is no significant hysteresis in the isotherms. It can be noticed from these figures that N_2 adsorption quantity increases with the increase of the activation temperature and KOH ratio. Total specific surface area, external surface area, total pore volume, micropore volume, and average pore width are evaluated using alpha-s method from N_2 adsorption isotherm.

Fig. 5 Pore size distribution of WPT-derived ACs.

Fig. 6 Pore size distribution of M-derived ACs.

Non-local density functional theory (NLDFT) has been used to estimate pore size distribution. Figs. 5 and 6 show the pore size distribution of WPT and M-derived samples, respectively. The vertical axis represents the differential pore volume with respect to pore width (dV_p/dW) whereas horizontal axis signifies the differential pore width. It can be seen from these figures that pore size distribution changes with the change of activation conditions. Most of the pores are found less than 5 nm in size.

The physical characterization results such as total specific surface area, external surface area, total and micropore volume, and average pore size of all synthesized samples are summarized in Table 2. From the experimental analysis, it is found that carbonization at 500 and 600°C, activation at 900°C, and six times KOH ratio produce highest total surface area and pore volume for both types of biomass-derived ACs. It can be observed that the surface area for both kinds of ACs increases with the increase of activation temperature (Table 2). At activation temperature 600°C, the surface area of WPT-AC is found to be 1402 m² g⁻¹. However, after increasing the activation temperature, it increases to a large value. The surface area is found almost saturated beyond the activation temperature 700°C even though the carbonization temperature and KOH ratio are changed in case of WPT-derived ACs. The maximum surface area is found about 2985 m² g⁻¹ in the case of WPT-derived AC named as WC500A800K4. Similar phenomena is also observed in the case of M-derived ACs as can be seen from Table 2. However, at the condition C500A600K4, the surface area of WPT-derived AC (WC500A600K4) shows very less compared to M-derived AC (MC500A600K4). It is observed that surface area is almost saturated beyond the activation temperature 600°C even though the carbonization

Table 2 Physical properties of synthesized WPT and M-derived ACs

MC600A900K6	2924	34.19	2.13	2.18	1.47

^aW: Waste palm trunk (WPT); M: Mangrove; C: Carbonization temperature in $^{\circ}\text{C}$ (for example: C500 means carbonization at 500°C); A: Activation temperature in $^{\circ}\text{C}$ (for example: A600 means activation at 600°C); K4 and K6: 4 and 6 times KOH of carbonized sample.

**Fig. 7** Thermal conductivity results of WPT-derived ACs.

temperature and KOH ratio are changed in case of M-derived ACs. The maximum surface area is found about $2925 \text{ m}^2 \text{g}^{-1}$ in the case of M-derived AC named as MC500A900K4. It is also noticed that at high activation temperature and KOH ratio, surface area for both the samples is nearly the same (Table 2).

The pore volume and average pore size also increase with the increase of activation temperature and KOH ratio for both type of samples. The WPT-derived ACs show higher pore volume and pore size compared to M-derived ACs. The highest pore volume is found to be $2.87 \text{ cm}^3 \text{g}^{-1}$ from WPT whilst $2.68 \text{ cm}^3 \text{g}^{-1}$ from mangrove, these values are the current benchmark. It is highlighted that synthesized biomass-derived ACs show superior porous properties compared to the literature value where the ACs were mostly derived from coal, coke, petroleum residue and different biomass sources (Himeno *et al.*, 2005; El-Sharkawy *et al.*, 2006, 2014; Danish and Ahmad, 2018).

Thermal Conductivity of Biomass-Derived ACs

Figs. 7 and 8 show the thermal conductivity results of WPT and M-derived ACs, respectively. As can be seen from these figures, thermal conductivity slightly decreases with the increase of activation temperature for all kinds of samples because of forming pores

Fig. 8 Thermal conductivity results of M-derived ACs.

into the AC. Large surface area and pore volume reduce the sample density, which might decrease the conductive network. Thermal conductivity values are found in the range of 0.054–0.041 W m⁻¹ K⁻¹ for WPT-derived ACs whilst 0.061–0.045 W m⁻¹ K⁻¹ for M-derived ACs.

Adsorption Performance of Biomass-Derived ACs

Adsorption Isotherm Model

Adsorption characteristic is considered the crucial parameter for designing the AHP systems. The behavior of equilibrium adsorption uptake for a particular refrigerant (adsorbate) entirely depends on adsorbent porous properties. The experimental adsorption uptake for a particular pair is usually correlated with well-known adsorption isotherm models to find the best fitting model. The fittings parameters are usually used to predict the system performance for an adsorbent/adsorbate pair. The commonly used adsorption isotherm models for activated carbon based adsorbents are presented in the following Eqs. (1)–(6).

$$\text{Freundlich: } \frac{W}{W_0} = \left(\frac{P}{P_s} \right)^{1/k} \quad (1)$$

$$\text{Langmuir: } \frac{W}{W_0} = \frac{b_0 e^{\frac{Q_{st}}{RT}} P}{1 + b_0 e^{\frac{Q_{st}}{RT}} P} \quad (2)$$

$$\text{Dubinin – Astakhov (D – A): } W = W_0 \exp \left[- \left(\frac{RT}{E} \ln \left(\frac{P_s}{P} \right) \right)^n \right] \quad (3)$$

$$\text{Dubinin – Radushkevich (D – R): } W = W_0 \exp \left[- \left(\frac{RT}{E} \ln \left(\frac{P_s}{P} \right) \right)^2 \right] \quad (4)$$

$$\text{Tóth: } \frac{W}{W_0} = \frac{b_0 e^{\frac{Q_{st}}{RT}} P}{\left(1 + \left(b_0 e^{\frac{Q_{st}}{RT}} P \right)^h \right)^{1/h}} \quad (5)$$

Dubinin-Astakhov (D-A) for high pressure gas (such as CO₂) adsorption:

$$q = \left(\frac{q_0}{v_m} \right) \exp \left[- \left(\frac{RT}{E} \ln \left(\frac{P_s}{P} \right) \right)^n \right] \quad (6)$$

where W is the equilibrium uptake [g g⁻¹ or kg kg⁻¹], W_o represents the maximum equilibrium uptake [g g⁻¹ or kg kg⁻¹], P is the equilibrium pressure [kPa or MPa], P_s represents the saturated vapor pressure [kPa or MPa], T denotes the adsorption temperature [°C or K], R is the gas constant [J mol⁻¹ K⁻¹], Q_{st} is the isosteric heat of adsorption [kJ mol⁻¹], k is the exponent of Langmuir equation, h is the dimensionless Tóth parameter known as heterogeneity factor, n is the exponent of D-A and modified D-A equations, q denotes volumetric adsorption uptake [cm³ g⁻¹], and q_0 is the maximum volumetric adsorption capacity [cm³ g⁻¹].

The adsorbed phase volume V_m of adsorbate in the Eq. (6) can be calculated using the Eq. (7).

$$V_m = V_t \exp (\alpha^* (T - T_t)) \quad (7)$$

At triple point, the value of parameter V_t of liquid carbon dioxide is 0.84858 cm³ g⁻¹. The thermal expansion α^* of the adsorbed gas is 0.0025 K⁻¹ as suggested by Saha *et al.* (2011), and Himeno *et al.* (2005). In the Eq. (6), the saturation pressure P_s above the critical temperature is calculated by means of pseudo-saturated vapor pressure as given by the Eq. (8).

$$P_s = \left(\frac{T}{T_c} \right)^z P_c \quad (8)$$

where P_c and T_c are the critical pressure [kPa or MPa] and temperature [°C or K] of the high pressure gas, respectively. If the exponent $z = 2$ of the Eq. (8), then the Eq. (6) is called classical D-A. Otherwise ($z \neq 2$), the Eq. (6) is called the modified equation proposed by Amankwah and Schwarz (1995).

Ethanol Adsorption Performance

Ethanol is considered one of the promising refrigerants or working fluids for adsorption cooling applications. In addition, ethanol work as a very good adsorbate for activated carbon (Pal *et al.*, 2017b). Consequently, this article focuses on measuring the adsorption performance of ethanol onto synthesized biomass-derived ACs. To understand the adsorption performance, one sample from each kind of biomass has been chosen, namely WC600A900K6 (WPT-AC) from WPT and MC600A900K6 (M-AC) from mangrove since they possess excellent porous properties. Equilibrium ethanol adsorption uptakes onto WPT-AC and M-AC are measured gravimetrically using magnetic suspension adsorption measurement unit (Rubotherm: MSB-VG-S2) explained in Section "Methodology for Adsorption Uptake Measurement". The details of the experimental procedure for ethanol adsorption can be found elsewhere (Pal *et al.*, 2017c).

Adsorption uptakes of ethanol onto WPT-AC and M-AC are measured at five different temperatures 30, 40, 50, 60, and 70°C with various evaporator pressures. Figs. 9 and 10 represent the measured adsorption uptake data of ethanol onto WPT-AC

Fig. 9 Adsorption isotherms of ethanol onto WPT-AC (WC600A900K6) (data are fitted with Freundlich, Langmuir model, D-A equation, and Tóth model). Reproduced from Pal, A., Kil, H.-S., Mitra, S., *et al.*, 2017a. Ethanol adsorption uptake and kinetics onto waste palm trunk and mangrove based activated carbons. *Applied Thermal Engineering* 122, 389–397.

Fig. 10 Adsorption isotherms of ethanol onto M-AC (MC600A900K6) (data are fitted with Freundlich, Langmuir model, D-A equation, and Tóth model). Reproduced from Pal, A., Kil, H.-S., Mitra, S., *et al.*, 2017a. Ethanol adsorption uptake and kinetics onto waste palm trunk and mangrove based activated carbons. *Applied Thermal Engineering* 122, 389–397.

Table 3 Fitting parameters of the studied isotherm models for ethanol adsorption onto WPT-AC and M-AC samples

Model	Fitting parameter	WPT-AC (WC600A900K6)	M-AC (MC600A900K6)
Freundlich	W_0 [kg kg ⁻¹]	2.2	1.9
	k [dimensionless]	1.4	1.7
	RMSD [%]	25.8	52
D-A	W_0 [kg kg ⁻¹]	1.9	1.65
	E [kJ kg ⁻¹]	91.55	105.91
	n [dimensionless]	1.43	1.62
Langmuir	RMSD [%]	5.43	3.40
	W_0 [kg kg ⁻¹]	2.6	2.2
	Q [kJ mol ⁻¹]	45.4	47.66
Tóth	b_0 [kPa ⁻¹]	3.18×10^{-9}	1.91×10^{-9}
	RMSD [%]	19.6	30
	W_0 [kg kg ⁻¹]	1.9	1.65
Tóth	Q [kJ mol ⁻¹]	44.23	46.30
	h [dimensionless]	3.88	3.42
	b_0 [kPa ⁻¹]	4.09×10^{-9}	2.37×10^{-9}
	RMSD [%]	5.13	8.24

Note: Pal, A., Kil, H.-S., Mitra, S., *et al.*, 2017a. Ethanol adsorption uptake and kinetics onto waste palm trunk and mangrove based activated carbons. *Applied Thermal Engineering* 122, 389–397.

(WC600A900K6) and M-AC (MC600A900K6), respectively. The experimental data are fitted with Freundlich, Langmuir, D-A (Dubinin-Astakhov), and Tóth models which are plotted on the same figure. It is found that D-A and Tóth models are fitted well with the experimental data compared to other studied models. The maximum equilibrium ethanol uptake onto WPT-AC is as high as 1.90 kg kg⁻¹ whilst one kg of M-AC can adsorb up to 1.65 kg of ethanol, these are the highest uptake compared to literature reported AC powder or fiber such as Maxsorb III, ACF-20, and ACF-15. The fitting isotherm parameters for all the studied models are presented in Table 3.

CO₂ Adsorption Performance

The CO₂ (R744) is chosen as a refrigerant or working fluid in adsorption cooling/heating applications because it provides numerous benefits including high volumetric capacity and availability. Furthermore, it is a nonflammable, non-toxic refrigerant having zero ODP and zero GWP. In addition, CO₂ also shows good affinity toward the AC. Therefore, many researchers focused on AC/CO₂ pair for adsorption heat pump systems and CO₂ capture or storage.

The magnetic suspension adsorption measurement unit (MSB-GS-100-10M), which is illustrated in Section “Methodology for Adsorption Uptake Measurement”, is used for the measurement of adsorption uptake of CO₂ onto WPT and M-derived ACs. The details of the experimental procedure for CO₂ adsorption measurement can be found elsewhere (Pal *et al.*, 2016; Jribi *et al.*, 2017). Equilibrium adsorption uptakes of CO₂ onto the WC600A900K6 (WPT-AC) and MC600A900K6 (M-AC) are investigated at four different adsorption temperatures namely 30, 40, 50, and 70°C with pressure up to 7 MPa. The plot of experimental data along with isotherm models for WPT-AC/CO₂ and M-AC/CO₂ pairs are presented in Figs. 11 and 12, respectively. The maximum absolute uptakes are found 2.3 cm³ g⁻¹ for WPT-AC/CO₂ and 2.1 cm³ g⁻¹ for M-AC/CO₂ pair, respectively, using a modified D-A model. The isotherm fitting parameters for the studied models for all ACs/CO₂ pairs are summarized in Table 4. It is highlighted that synthesized biomass-derived ACs shows highest adsorption uptake of CO₂ compared to all other ACs such as Maxsorb III, Norit RB3, Norit darco, BPL, A-20, A-10, reported in the literature.

Fig. 11 CO₂ adsorption onto WPT-AC (WC600A900K6) and data are fitted with (a) Tóth model, and (b) modified D-A model.

Fig. 12 CO₂ adsorption onto M-AC (MC600A900K6) and data are fitted with (a) Tóth model, and (b) modified D-A model.

Table 4 Fitting parameters of the studied isotherm models for biomass-derived ACs/CO₂ pairs

Model	Fitting parameter	WPT-AC (WC600A900K6)	M-AC (MC600A900K6)
Modified D-A model	q_0 [cm ³ g ⁻¹]	2.2775	2.1321
	E [J mol ⁻¹]	3995.67	4322.67
	k [dimensionless]	4.437	4.749
	n [dimensionless]	1.20	1.15
	RMSD [%]	4.118	2.975
Tóth	W_0 [g g ⁻¹]	3.50	3.20
	Q [J mol ⁻¹]	17,685.23	18,473.66
	h [dimensionless]	1.1743	1.1286
	b_0 [MPa ⁻¹]	1.577×10^{-4}	1.290×10^{-4}
	RMSD [%]	3.967	3.348

Conclusions

In this article, activated carbons are synthesized and found to be excellent porous properties from two waste biomasses, namely, waste palm trunk and mangrove. N_2 adsorption/desorption isotherms show that biomass-derived ACs have a high degree of porosity which is located mainly in micro size of pores. ACs with a surface area between 1402 and 2985 $m^2 g^{-1}$ having pore volume 0.65–2.87 $cm^3 g^{-1}$ are successfully prepared from both type of biomasses. It is worthy to mention that the highest surface area and pore volume of WPT-derived ACs are found to be 2985 $m^2 g^{-1}$ (WC500A800K4) and 2.87 $cm^3 g^{-1}$ (WC500A900K6) and for M-derived ACs it is 2925 $m^2 g^{-1}$ (MC500A900K4) and 2.68 $cm^3 g^{-1}$ (MC500A900K6), respectively. The porous properties achieved in this study are the highest compared to the reported literature data which is a current benchmark. Generally, the increase of the activation temperature and the mass ratio of KOH/carbon can enhance the porosity. However, the micropore is widened when the activation temperature and mass ratio of KOH/carbon is increased. It is found that all the porous properties are saturated at a certain synthesis condition and decreases at higher temperature and KOH ratio. It can be summarized that carbonization at 500 and 600°C, activation at 900°C, and six times KOH ratio produce the highest surface area and a pore volume from both kinds of biomasses. Therefore, WC500A900K6, WC600A900K6, MC500A900K6, and MC600A900K6 can be selected as promising adsorbents among the synthesized ACs for various energy conversion applications. Experimental results show that thermal conductivity values ranging from 0.054 to 0.041 $W m^{-1} K^{-1}$ is for WPT-derived ACs whilst 0.061–0.045 $W m^{-1} K^{-1}$ is for M-derived ACs. The synthesized biomass-derived ACs show highest adsorption uptake of ethanol and CO_2 than that of reported data in the literature. The maximum equilibrium ethanol and CO_2 uptakes onto WPT-AC are found to be as high as 1.90 $kg kg^{-1}$ and 2.3 $cm^3 g^{-1}$, respectively and thus are very promising for energy conversion and storage applications.

Introduction

In various engineering applications, the surface properties of engineering components are enhanced using surface modification technology. As a consequence, the interest in surface engineering has risen greatly throughout the past decades. Surface engineering involves the development of a new or modified exterior phase on the substrate material (Chattopadhyay, 2014; Hardell and Prakash, 2010). Through surface engineering, the thin near-surface layer of substrate material is modified while maintaining their core structure and properties (Bello *et al.*, 2016; Dong, 2010; Mridha and Dyuti, 2011).

The surface melting technique also known as cladding which has been widely used as surface engineering technology. The surface melting technology involves of high energy source that is applied to melt the surface of the substrate fed with reinforcing particles (Sathiya *et al.*, 2009). Upon solidification, the reinforcement is strongly bonded with the substrate material. Powder blown, wire feed and pre-place powder are the three methods to feed the reinforcement onto the substrate material prior or during the surface melting technology (Folkes, 1994).

Various surface engineering technologies were introduced by previous researchers through several famous approaches such as tungsten inert gas welding (TIG) (An *et al.*, 2017; Bello *et al.*, 2016; Kumar *et al.*, 2017; Maleque *et al.*, 2017; Sahoo and Masanta, 2017a,b; Saroj *et al.*, 2017a,b), laser cladding (Qunshuang *et al.*, 2017; Yang *et al.*, 2016; Zhou *et al.*, 2016), electron beam welding (EBW) (Lienert *et al.*, 1993; Peng *et al.*, 2011) and thermal spraying (Aussavy *et al.*, 2014; Shibe and Chawla, 2014). Tungsten inert gas welding (TIG) melting technology or also commonly known as gas tungsten arc welding (GTAW) has started to be used during the Second World War. TIG torch technology was designed by Russel Meredith and developed by Linde Company. After several years of development, it was finally modified in 1941 and patent issued in 1942. The heat in TIG melting technology is initiated from an electric arc between the tungsten electrode and substrate material. The melting of substrate surface is protected from contamination using common protective gases such as helium, argon or the mixture of them. The following solidification of the substrate material fed with reinforcement particle produced new intermetallic compound with altered wear and hardness behavior (Maleque *et al.*, 2018; Musa *et al.*, 2018; Mridha *et al.*, 2012a,b).

Another surface melting technology known as electron beam welding (EBW) was developed in 1950s. The kinetic energy of accelerated electrons is used as the heat source for surface melting process in this technique. The generation of high velocity electrons is performed by heating the negative-charged cathode filament up to its thermionic emission temperature. The electron beam with diameter between 0.3 and 0.8 mm hit the base material with velocity up to 70% of the speed of light. Around 95% of the electron's kinetic energy is generated into heat. The power density is up to 10^{10} Wm^{-2} . The superior power density makes EBW capable of deep melting of the substrate surface. This could be an good to fused two metals together, however, surface melting technique does not need such high heat source since the purpose is to modify only the thin near surface layer of the substrate (Sun and Karppi, 1996).

Laser cladding is a recent surface engineering technology where another substance is combined onto the substrate surface for surface modification. Laser cladding is considered as one of the surface melting technology. The fusion of reinforcement particles onto the substrate surface is done using laser as heat source. The method was developed in 1970s and usually used as utility to repair and enhance the surface of engineering parts (Gedda, 2004). The modified layers produce by this method is said to have strong metallic bond, low dilution and less distortion between the reinforcement and the substrate (Huang *et al.*, 2010; Zanzarin *et al.*, 2015). Fernández *et al.* (2014) recommended to control the surface coating thickness by varying the process parameters of laser cladding.

Thermal spraying is a surface engineering technology developed in 1910s to 1920s where the reinforcement materials is melted, sprayed and latched onto the substrate surface. From the same category, a common surface engineering technology known as plasma spraying is developed in 1970s where a high temperature (can exceed 15000K) plasma jet is used to spray refractory materials for examples, oxides and high melting point metals such as molybdenum (Seiji *et al.*, 2008). The deposited reinforcement particles solidify and form laminar structure of the new modified layer (Aussavy *et al.*, 2014; Begg *et al.*, 2016; Seiji *et al.*, 2008; Shibe and Chawla, 2014). The method highly depends on the cleanliness and roughness of the substrate surface. Therefore, surface preparation prior to the surface melting process is very crucial. Furthermore, the grit blasting is usually used on the substrate surface to allow adhesive bonding with the reinforcement. However, grit blasting require more labor and the surface finish for the method is said to be non-consistent (Begg *et al.*, 2016).

Among the surface engineering technology discussed previously, TIG torch surface melting technology is believed as crucial key in the development of the surface modification technology due to its simplicity, flexibility and cheap establishment. The method was used in the world war era by the military on stainless steel, aluminium and magnesium for aircraft components. TIG torch melting now is used in numerous applications in aerospace, automotive, nuclear reactors, ship, civil parts etc. TIG torch technique

can be used not only on the stainless steel, magnesium and aluminium, but also used for other type of alloy steels (low alloy steel, high alloy steel, duplex stainless steel, microalloyed steel etc.), magnesium composite, aluminium composite, titanium and its alloys.

A lots of processing parameters in TIG torch surface melting technology has to be taken into consideration such as the current and voltage applied, welding speed, shielding gas type, composition and flow rates, and powder preplacement rate (Maleque and Afiq, 2018; Bello *et al.*, 2015; Maleque *et al.*, 2015). The varying parameters is optimized to get the best behavior required for demanded applications (Cheniti *et al.*, 2017; Jarial, 2015; Korra and Balasubramanian, 2011; Maleque *et al.*, 2017; Peng, 2012; Srirangan and Paulraj, 2016). Overall, it was found that the methods utilized by previous researchers were beneficial to improve the surface performance of various substrate materials which include their wear, hardness, coefficient of friction and corrosion resistance. The aim of this paper is to review and emphasis the importance of TIG torch melting as surface engineering technology.

Melting Approach in Surface Engineering

Melting route also known as fusion is a technique that utilize high melting heat to form melt layer with metallurgical bonding upon solidification. The use of melting route in surface engineering highly increases when the electric energy was revealed. Fig. 1 shows the evolution of the surface melting route that is rapid began in 18th century. The melting route can be used to fuse the ceramic particles reinforcement and substrate material together and hence modify the thin surface layer for better hardness, friction and wear behavior. The reinforcement used in this melting route is usually ceramic particles since they have high degree of hardness and high thermal stability. Therefore, the superior properties of ceramic particles as reinforcement are beneficial to the surface performance of the metallic substrate.

There are three methods to feed the ceramic reinforcement into the substrate surface in the surface melting process; powder injection or blown, wire feed and powder preplacement method as shown in Figs. 2–4 respectively. For powder injection or blown method, the reinforcement particles are carried using a blow of gas that are commonly argon, CO₂ or oxygen. The reinforcement particles are fed through coaxial or lateral feed method. The stream of carrier gas should be maintained well to produce good quality of surface coating layer with uniform distribution of reinforcement. If the gas flow rate is too high, this might decrease the heat input on the substrate surface and leads to less dissolution of particles. When the gas flow rate is lower, less quantity of reinforcement particles reaches the melted surface.

Surface melting approach in surface engineering also can be conducted using wire feed method as shown in Fig. 3 where the spool containing filler or reinforcement particles are fed through a nozzle onto the substrate surface. The wire feed which is used to transport the reinforcement should have no defects that might disturb the flow consistency and affect the quality of the coating layer. For example, when the wire feed is dented, the reinforcement particles deviates from getting into the centre of the melt layer. The quality of the melted layer also is highly depended on the wire feed rate. For instance, slower wire feed rate causes some amount of the reinforcement unable to reach the centre of the melt layer. According to previous authors, wire feed method does not waste the reinforcement material used as compare to the powder injection method (Kou, 2003; Toyserkani *et al.*, 2005).

Another way to conduct surface melting technique is by introducing powder preplacement method as shown in Fig. 4. Powder preplacement method is the cheapest, simple, flexible way to perform surface modification of metallic materials and able to produce good quality of coating layer with strong metallurgical bonding. Polyvinyl acetate (PVA) solution is used in powder preplacement method as a binder to keep the powder from blown away by shielding gases during melting process. The amount of

Fig. 1 Development of surface melting process over the years.

Fig. 2 Powder blown reinforcing method.

Fig. 3 Wire feed reinforcing method.

Fig. 4 Powder preplacement reinforcing method.

binder solution is controlled since high amount of binder result in porosity during solidification of the coating layer. High heat input then is applied after the powder preplacement process to melt the reinforcement and substrate surface together. The melted reinforcement and substrate surface forms intermetallic compound upon solidification with new microstructure and altered physical and other properties.

Based on previous discussion, each of the surfacing methods such as powder blown or injection method, wire feed and powder preplacement method have their own mechanism to feed the reinforcement particles onto the substrate surface for surface melting process. The end quality of the coating surface layer is affected by processing parameters which is unique for each of the surfacing method. Overall, powder preplacement process is favorable since it is the cheapest, simple, and flexible and easily controls to produce decent quality of surface melt layer.

TIG torch surface melting technology which utilized powder preplacement process mentioned previously are recently used by various researchers (Adeleke *et al.*, 2015; Maleque and Afq, 2018; Muñoz *et al.*, 2017). The technique uses heat that is generated from an electric arc produced between the tungsten electrode and the metal substrate. Upon melting and solidification of the substrate and ceramic reinforcement, a new intermetallic compound is formed with modified metallographic structure and properties. Argon is commonly used in TIG torch surface melting technology to control the weld environment and thus preventing contamination and oxidation. The advantages of the technique include high surface quality, inexpensive establishment with easy control of the system, low installation and maintenance cost, can be used on a wide range of materials and usually small flames or

sparks is used during melting process which leads to less amount of distortion in the substrate material. However, TIG torch surface melting technology is a slow process, with low deposition rate and it is not suitable for thicker material due to its small amount of heat source (Bello *et al.*, 2015; Lailatul and Maleque, 2017; Maleque and Adeleke, 2013; Musa *et al.*, 2018).

Materials for TIG Torch Surface Melting Technology

TIG torch is most frequently used to weld thin sections of stainless steels and nonferrous metals for instances aluminium, magnesium, nickel and copper (Panigrahi and Sarangi, 2017). Recently, several research works have been conducted on TIG torch surface melting that produces positive results in terms of surface morphology, wear and hardness behavior. (Adeleke and Maleque, 2015; An *et al.*, 2017; Ardeshiri *et al.*, 2017; Ghaffari *et al.*, 2016; Lailatul and Maleque, 2017; Mridha and Baker, 2015a; Muñoz *et al.*, 2017; Stadler *et al.*, 2017).

Alloy steels are the most common reported materials used in TIG torch surface melting technology. Muñoz *et al.* (2017) successfully developed metal matrix composite layer on a microalloyed steel surface by dissociating MAX211 Ti₂AlC particles using a TIG torch technique. Other work using TIG torch surfacing was done by Mridha and Baker (2015a) on low alloy steel surface using titanium carbide (TiC) as reinforcement powder. Stadler *et al.* (2017) study the influence of welding parameters on the weld pool dimensions and shape in a TIG configuration using AISI 304L stainless steel. Bello *et al.* (2016) successfully developed TIG-alloyed hybrid composite coating on AISI 4340 low alloy steel substrate. Lailatul and Maleque (2017) have modified the surface of duplex stainless steel with SiC preplacement using TIG torch cladding.

Mridha and Baker (2015b) also utilized the TIG torch surfacing to examine the corrosion resistance of titanium aluminide coating on pure titanium substrate. The hardness of the surface alloyed layer was found at 400–600 HV_{0.5kgf} which is higher than the substrate hardness (180 HV_{0.5kgf}). The surface alloyed layers also exhibited six times higher oxidation resistance compared to the titanium substrate. Adeleke and Maleque (2015) study the deposition of powder blends of Fe, Si and C on pure titanium Grade 2 by TIG torch surfacing technique to enhance its wear resistance properties. An *et al.* (2017) have performed the TIG torch surfacing on titanium alloy Grade 5 using TiB reinforcement to study the microstructure developed and mechanical performance of the new modified surface. The maximum hardness obtained for the new developed TiB₂/Ti-6Al-4V composite was 800 HV_{0.2kgf} which is 128% higher than the Ti-Al-4V alloy substrate. The coefficient of friction for the new surface of TiB₂/Ti-6Al-4V composite is 0.36 which is also considerably lower than the substrate (0.48). It can be concluded that the TIG torch surface melting is a potential low cost method to improve the surface properties of Ti-6Al-4V alloy.

Surface alloying of A2618 aluminium alloy by Ardeshiri *et al.* (2017) was carried out by pre-placing powder blend of silicon and iron and subsequent TIG process. Surface alloying of AZ31 magnesium alloy was also performed using TIG torch surfacing by Ghaffari *et al.* (2016). The coating reinforcement materials used are the same as previous authors i.e., a mixture of silicon and iron.

Overall, TIG torch surfacing technique can be utilized on almost all metals except zinc and its alloys. This is due to very little difference between the melting and boiling point of zinc and thus could vaporized during TIG welding process. The fumes released are also toxic and hazardous to health (Weman, 2003). However, the surfacing technique is suitable to be used on a wide range of metallic materials including various grades of alloy steels, nonferrous materials such as titanium, aluminium and magnesium and their respective alloys or composite.

Parameters for TIG Torch Surface Melting Technology

Processing parameters are known to have very crucial effect on the quality of the new surface coated layer. Optimization of the melt structure quality often required time and effort. In TIG torch surface melting technology, welding current and voltage, shielding gas flow rate, arc gap and electrode welding speed are known as the main parameters leads to a better surface coated layer. The composition and amount of ceramic particles added also can be varied to control the surface properties required. Some works was done by previous researches on the optimization of the melting process for the surface modification. For example, Bello *et al.* (2015) conducted experimental work on the hardness performance of low alloy steel reinforced with TiC using TIG torch surface melting technology. The effects of welding current and voltage, electrode travelling speed and argon flow rate were analyzed using Taguchi's experimental design. It was found that the welding voltage and electrode travelling speed were more significant parameters than the others as can be seen from Table 1 which shows the Signal to noise (S/N) ratio response analyzed from Minitab software. The significant of the processing parameters depend on the difference between the maximum and minimum delta value. Higher delta value signify higher influence on the respective processing parameters. Hence, from Table 1, it is found that the welding voltage and speed are more crucial in defining the hardness behavior of the low alloy steel.

In similar field, the optimization of TIG torch surface melting was performed on AISI 4340 alloy steel incorporated with TiC particles through Taguchi's design of experiment and analyzed by MINITAB 17 statistical software (Maleque *et al.*, 2017). Similar results obtained where the welding voltage and welding speed are found to be more significant in determining the wear performance of the alloy steel substrate. Another report by Kou (2003) analyzed the effect of welding speed and current on the TIG torch surfacing of HY-80 steel. It was found that the microstructure of the surface melted layer consist of dendritic structure as the applied current is increased with welding speed kept constant. It is also reported that the cooling rate was faster when the welding speed was increased with applied current kept constant. This leads to a finer dendritic structure. Mridha *et al.* (2012a,b) also

Table 1 S/N response table for surface hardness

Levels	Welding current	Welding speed	Welding voltage	Argon flow rate
1	57.13	56.94	57.43	57.20
2	56.88	56.50	56.39	56.69
3	56.77	56.64	56.76	56.80
4	56.69	57.40	56.89	56.81
Delta	0.44	0.9	1.04	0.51
Rank	4	2	1	3

Note: Bello, K., Maleque, M., Ahmad, Z., Mridha, S., 2015. Optimization of hardness behavior of TIG modified ceramic coating using the Taguchi approach. Adv. Mater. Res. 1115, pp. 238–242.

conducted TIG surface melting technology on steel alloys and reported the effect of welding voltage applied. It was observed that when the welding voltage is varied between 30 V and 55 V, the developed microstructure and the hardness of the surface melted layer changed significantly.

Other than that, the effect of shielding gases as processing parameter in TIG surface melting technology have been reported which included the types, gas flow rates and the gas composition (Hojjatzadeh *et al.*, 2012; Vaziri *et al.*, 2012). The type of shielding gas used is found to significantly affect the current density. The common shielding gas used is argon, helium or mixture of them. It is observed that the use of argon leads to stable electric arc and less possibility of ionization. Other several researchers also agreed with the effectiveness of using argon gas as protective gas in TIG torch surface melting (Idriss and Mridha, 2012; Maleque and Sugrib, 2013; Mridha *et al.*, 2012a,b; Wang *et al.*, 2017). Utsumi *et al.* (2001) on the other hand studied the effect of protective gas flow rates on the melted layer dimensions and geometry. It was found that the dimension of the melt pool was larger when higher gas flow rate was used.

Overall, it can be said that TIG torch surface performance characteristics depend on a range of crucial processing parameters from welding voltage and current, electrode travelling speed, current supply technique (pulsed or continuous), preplaced powder content and composition, working distance, shielding gas types, composition and flow rates. Each of the individual without doubt has significant effect on the surface performance of the new modified surface layer. However, welding current, voltage and speed which are basically what made up the heat input, play more crucial role in the optimization of TIG torch surface melting compared to the other processing parameters.

TIG Surface Melting Technology: A Success Story

Carbides, borides and nitrides are the most common reinforcement powders utilized in surface engineering technology. Numerous works were reported on using such reinforcement materials for instances tungsten carbide (WC) (Abioye *et al.*, 2016; Mottaghi and Ahmadian, 2017; Niu *et al.*, 2010; Wang *et al.*, 2018a,b; Zhang *et al.*, 2017), silicon carbide (SiC) (Amirkhanlou and Niroumand, 2012; Cheniti *et al.*, 2017; Khodaei *et al.*, 2018; Moradkhani and Baharvandi, 2018; Ozben *et al.*, 2008), boron carbide (B₄C) (Khan *et al.*, 2018; Li *et al.*, 2018; Moradkhani and Baharvandi, 2017) and a titanium carbide (TiC) (Fattahi *et al.*, 2015; Jin and Plucknett, 2018; Saroj *et al.*, 2017a; Wang *et al.*, 2018a,b). Metal carbides such as TiC, CrC and SiC normally have higher wear resistance, higher degree of hardness, higher melting point and lower coefficient of friction. Another report also mentioned that the transition metal carbides/iron matrix composites are known for their resistance to abrasion, oxidation, and corrosion and they are broadly used in harsh environments in various industries such as mining and mineral processing, cement production, and pulp and paper manufacture (Ye *et al.*, 2015). Based on a numerous research works conducted by authors mentioned earlier, the use of these preplacement of metal carbides on the surfacing of metallic materials enhance their surface performance characteristics. In the following sections, a success stories is presented whereby TIG torch surface melting technology was employed.

Adeleke and Maleque (2015) have been successfully used TIG torch surface melting technology on commercially pure titanium (Cp-Ti). The reinforcement particles used were iron-silicon-carbon powders varied at three different compositions: 97Fe2C1Si (named as PPM1), 94Fe4C2Si (named as PPM2) and 91Fe6C3Si (named as PPM3). The substrate surface was ground first using emery paper to eliminate oxide layer and other contaminant. This ensures proper bonding between the reinforcement powder and substrate during melting process. Then, the reinforcement powder was preplaced on the substrate surface with the same preplacement rate for the three compositions prior to the TIG torch melting process. The current used is 100 A with heat input of 1350 J/mm. The microstructure, hardness and the wear behavior of the TIG torch melted surface modified Cp-Ti were examined.

From the results obtained, it was observed that when PPM2 powder was used, the weld pool was wider and deeper. This is due to thicker carbide formation which lead to more heat released and hence, larger weld pool. Defects were observed on the melt pool when PPM3 powder was used. This is related to the increased in the amount of powder used. The larger quantity of silicon leads to the formation of ferrite microstructure whereas the larger quantity of carbon leads to dendrite structure formation which is observed in PPM2 preplacement track as shown in Fig. 5. From EDX analysis as shown in Fig. 6(a), the dendrites structures exhibited TiC phase. This is due to larger affinity between Ti and C than the Fe and Si element. From Fig. 7(a) it was found that composition of PPM2 on the surface modification of Cp-Ti show highest degree of hardness ~800 HV_{0.5kgf}. This is multiple times

Fig. 5 SEM images of the modified CP-Ti using different composition of reinforcement powder: (a) 97Fe2C1Si (PPM1), (b) 94Fe4C2Si (PPM2) and (c) 91Fe6C3Si (PPM3). Reproduced from Adeleke, S., Maleque, M., Mridha, S., 2015. Thin surface layers of iron-based alloys deposited by TIG hardfacing. *Tribol. Online*. 10, 434–440.

Fig. 6 (a) EDX analysis within the dendrite phase of new developed surface on PPM2 melt track as shown in Fig. 5(b), (b) Elemental analysis after dissolution of Fe, C, Si in Cp-Ti melt matrix and (c) X-ray diffraction pattern of PPM2 melt track at energy input 1350 J/mm. Reproduced from Adeleke, S., Maleque, M., Mridha, S., 2015. Thin surface layers of iron-based alloys deposited by TIG hardfacing. *Tribol. Online*. 10, 434–440.

(4 times) higher than the titanium substrate hardness which is only 200 HV_{0.5kgf}. For the PPM3 weld track, the hardness was recorded at 470 HV_{0.5kgf} which is related to the presence of defects and the unmelted reinforced powders in the weld pool. PPM2 welded track also represents lower wear rate resulting highest wear resistance. This is associated with the larger weld pool area and presence of hard carbides particles. For the PPM3 weld track, the wear resistance is the lowest, as a result from its low degree of hardness. The PPM1, PPM2 and PPM3 powders showed smaller friction of coefficient compared to the titanium substrate as shown in Fig. 7(c). Their coefficients of friction are 0.32, 0.26 and 0.39 respectively. This means that the addition of larger content of the powder composition leads to lower coefficient of friction. Overall, the TIG torch surface melting process was able to improve the hardness of pure titanium substrate up to 3–4 times. The wear, hardness and friction behavior were significantly improved especially when the reinforcement powder of PPM2 was used.

Fig. 7 (a) Microhardness of surface reinforced layer compared to the substrate, (b) Effect of different preplacement powder composition on the wear rate of TIG melted surface modified layer (c) Friction performance of TIG surface reinforced layer with different sliding speed for 30 min, at 200 RPM. Reproduced from Adeleke, S., Maleque, M., Mridha, S., 2015. Thin surface layers of iron-based alloys deposited by TIG hardfacing. *Tribol. Online*. 10, 434–440.

Conclusions

In a conclusion, TIG torch surface melting technology which used powder preplacement method shown to be beneficial in surface modification of engineering parts since it has inexpensive establishment with easy control of the system. It is found that TIG torch surface melting technique can be applied on various metallic materials and give positive results on the surface performance of the surface modified layer. Based on this study, it can be said that the parameters for TIG torch surface melting technology such as welding current, speed and voltage which made up the heat input are the most significant parameters compare to the other processing parameters. Finally, this surface melting technology can produce engineering parts with better wear, erosion and corrosion resistance behavior which can be used for high temperature applications.

Glossary

Coefficient of friction (COF) The ratio between the generated friction force to the applied normal force.

Tribology The study that deals with the design, friction, wear, and lubrication of interacting surfaces in relative motion as in bearings or gears (Merriam-Webster dictionary).

Introduction

In recent years, the applications of polymers for tribological purposes have been increasing. Understanding the tribological performance of polymers is critical for successful applications. The tribology of polymers is complicated. For example, friction is affected by load, sliding velocity and temperature, and wear can arise from abrasion, adhesion and fatigue (Myshkin *et al.*, 2005). Other environmental conditions such as lubricant, ambient composition, surface roughness, and abrasive particles can also affect the tribological performance (Nunez and Polycarpou, 2011; Lu *et al.*, 2017). Thus, it is hard to predict polymer tribological performance based on simple models, and it is wise to carry out laboratory experimental work which could simulate actual working conditions before deployment in the field. This is the main reason as to why tribology is largely dependent on experimental research, and universal models are non-existent. There are two important aspects that need to take into consideration: (1) Polymers used for tribological applications are typically polymer blends where the additives used tend to strengthen polymers, which are usually referred to as high bearing polymers, or simply polymer blends, and (2) Bulk polymers and polymer blends which could vary from a mm size in thickness to larger sizes suffer from creep and long-term performance. However, polymer blend coatings (of the order of few nanometers to 10s of microns) alleviate bulk polymer issues and take advantage of the strong metal backing/substrate.

Tribology of Polymers

Tribology is the science that deals with friction, wear and lubrication of interacting surfaces in relative motion. The friction force between two solids is usually attributed to adhesion and deformation effects; where the adhesion force involves the shearing between the real contact surfaces and deformation is due to the hard material asperities plowing in the softer material. Due to their low surface energy, low shear strength and low elastic modulus, polymers usually have low COF values. Polymers exhibit viscoelasticity, which is time and temperature dependent mechanical parameters. Specifically, the temperature is the flash temperature at the contact area and this flash temperature is related to normal load, sliding speed and the body temperature of the two contacting parts. Thus, the friction of polymers is largely affected by load, sliding velocity, and temperature (Myshkin *et al.*, 2005).

Wear of polymers and polymer blends are attributed to abrasion, adhesion and fatigue. Abrasive wear on the polymer surface occurs due to the asperities of the counter surface, the contaminant abrasive particles and also from the generated polymeric debris that get squashed between the surfaces and roll or slide on the counter surface; the hardness of the polymer debris could increase in the sliding process as a result of repeated plastic deformation, and then the polymeric debris could act as an abrasive particle itself (Zhang *et al.*, 2006). Adhesive wear is caused by the shearing at the real contact area where the joints break with removal of material due to adhesive forces. Cyclic loads (normal and friction forces) placed on the polymer can cause fatigue of the coating followed by nucleation and propagation of microcracks (Barletta, 2011), resulting in fatigue wear. However, some polymeric coatings show a unique property of generating a thin film/layer on the counter surface that could help better control of wear and friction.

Transfer layers are usually formed on the metal surface when polymers slide against metal, as shown in Fig. 1 (Demas *et al.*, 2008). The film was transferred during unidirectional pin-on-disk experiments using an ATSP/PTFE blend on to gray cast iron counter surface. For this experiment the sliding velocity was 2.4 m s^{-1} and the normal load was 222.4 N. These films could be uniform or patchy depending on, among other factors, the surface roughness of the sliding surfaces (Nunez and Polycarpou, 2015). Transfer films develop because of adhesion and interlocking of the fragments of material into metal asperities. Transfer film affects the wear performance. In this case, transfer film is responsible for the gradual transition from transient progressive wear behavior to steady state wear behavior. Wear occurs initially by the loss of material before a transfer layer is established on to the counter surface and also by the loss of transfer film because of its peeling from the counter surface (Bahadur, 2000). From a qualitative standpoint, sliding conditions such as velocity, load, atmosphere, roughness, and temperature are expected to affect the transfer film formation and destruction. Polycarpou and coworkers found that the surface topography of sliding surfaces and lubrication conditions affect the formation of the transfer layer (Yeo and Polycarpou, 2014).

Bulk Polymers and Polymer Coatings

In general, polymers can be used in bulk or coating forms in industrial applications. Polymers in bulk form have been widely used, such as the top layer (insert) for thrust tilting pad bearings, washers, and bushings. Usually polymers in pure form (referred to as unfilled polymers) may have high COF values, high wear rate and poor mechanical properties, so they do not satisfy engineering, and in particular bearing application requirements. Thus, researchers have produced composites or blended polymers by adding different fillers and reinforcements in the polymers, improving significantly their mechanical, thermal and tribological properties. For example, in the compressor industry different unfilled and filled polymers in bulk format were investigated as potential compressor bearing materials (Cannaday and Polycarpou, 2005).

However, polymers in bulk form have shortcomings such as low load capability and low dimensional precision, because of low stiffness and high thermal expansion; causing high surface temperature when sliding because thick polymers act as heat insulators; and cold creep. To maintain the bulk polymers' advantages and minimize their drawbacks, thin polymer coatings offer a potential solution. Moreover, thin polymer coatings would have lower cost because of their easy/inexpensive deposition methods and less material needed.

Advanced Polymeric Coatings

In general, coatings can be classified as either “hard” or “soft” coatings and polymer-based coatings belong to the “soft” coating category. The thickness of the polymeric coatings discussed herein is of tens of microns; due to such low thickness, their wear performance is very crucial.

Polymer coatings are widely used as tribological protective coatings, such as erosion/corrosion resistant coatings for automotive applications (Trezona *et al.*, 2000), transparent protective coatings for touch panel screens and optical applications (Masuko *et al.*, 2013), hydrophobic coatings for moisture repellent and dirt resistance (Khanjani *et al.*, 2017), bio-implant materials like artificial joints (Liu *et al.*, 2012), bearing materials for compressor bearings (Akram *et al.*, 2016) or thrust pad bearings (Heshmat *et al.*, 2005). This publication introduces some extreme experimental conditions for advanced bearing grade coatings.

Tribological Applications of Advanced Coatings

Air Conditioning and Refrigeration Compressors

Many types of compressors suffer catastrophic failures due to scuffing of their sliding metallic parts during starved lubrication or dry sliding, where insufficient amount of lubricant is available at the contact. Premature failures of various metallic tribopairs have been shown experimentally (Yoon *et al.*, 2000; Solzak and Polycarpou, 2010). In addition, the inevitable transition to new refrigerants due to environmental concerns, affected the tribological requirements of the sliding surfaces in compressors that are used in air-conditioning and refrigeration applications. Due to polymeric coating's proven performance in similar applications, several studies focused on the tribological performance of PEEK and PTFE blends under compressor-specific operating conditions (Yeo and Polycarpou, 2012). Results indicated COF values generally lower than 0.2 for PEEK and less than 0.15 for PTFE blends. Prevalent wear rates were in the range of 10^{-6} – 10^{-5} mm³ N⁻¹ m⁻¹. The wear mechanisms in polymeric coatings differ significantly compared to their bulk form, which are dominated by mild plowing and delamination. Generation of fine debris due to abrasion

and their role in material transfer to the harder counter surface has been highlighted in several relevant researches. Fig. 2 shows the debris generated due to the abrasion of a polyimide composite sliding against gray cast iron disk. The pin-on-disk configuration was used under unlubricated conditions, and the sliding velocity was 2.4 m s^{-1} and a contact pressure of 7 MPa was applied (Nunez and Polycarpou, 2015).

ATSP both in unfilled (pure) form and in its filled (blended with additives) exhibits superior performance in compressor applications (Zhang *et al.*, 2008). ATSP blended with PTFE (25/75) showed similar COF values compared to other state-of-the-art polymers such as PEEK and outperformed their wear resistance notably when tested in compressor operating conditions (Demas *et al.*, 2008). Fig. 3 depicts the wear and friction performance of some PTFE-based and PEEK-based coatings. PTFE-based coatings exhibited a better tribological performance compared to PEEK-based coatings under both reciprocating and unidirectional operating conditions corresponding to piston type and swash-plate compressors, respectively. Durability tests demonstrated the viability of PTFE/pyrrolidone coatings for oil-less compressors (Yeo and Polycarpou, 2012). A complimentary study conducted on different polymeric coatings under air-conditioning compressor operational conditions proved that ATSP/PTFE coatings outperform the other coatings in both dry and starved lubrication conditions in the presence of environmentally friendly r1234yf refrigerant. It was concluded that surface morphology and chemical composition of the top layers determine the tribological performance of the coatings under starved lubrication conditions (Akram *et al.*, 2016).

The combined effect of lubricant and refrigerant may deteriorate the wear and friction performance of polymeric coatings mainly due to the miscibility of the lubricant and the refrigerant, hindering the formation of effective transfer films, and sweeping away the plastically hardened debris from the contact area (Dascalescu *et al.*, 2009; Akram *et al.*, 2016; Yeo and Polycarpou, 2012).

Thrust Bearing Application

Close to 14% of electricity generated worldwide has been via hydro generation whose performance heavily depends on large thrust bearings (Liming *et al.*, 2017). Other applications include electrical submersible pumps (ESPs) used in oil & gas exploration. Due to the high load capacity and capability to operate at higher temperatures and lower film thickness, polymeric pads are viable alternatives for Babbitt, which is a common material for bearing pads in conventional tilting pad bearings (Glavatskih, 2003). Two of the most common polymers used as pad linings are PTFE and PEEK (Wodtke and Wasilczuk, 2016; Simmons *et al.*, 2014). Fig. 4 shows typical PTFE, PEEK, and ATSP lined pads. PTFE exhibits a low run-in friction and integrity of mechanical properties under high loads while PEEK when used as a composite maintains its mechanical properties at high operating temperatures up to 250°C. Other polymeric coatings were also tested for such applications including polyperfluoroalkoxyethylene (PFA) (Mahieux, 2005) and commercial polyimides (Nilsson and Prakash, 2013).

Others (Zhou *et al.*, 2015) tested PEEK lined tilting pad thrust bearings and reported higher load capacity and lower power loss for PEEK lined pads when compared to Babbitt pads. Tilting pads used in the oil & gas industry could also benefit from polymer linings. Lan *et al.* (2016b) showed that ATSP, PEEK and PTFE based coatings exhibit significant enhancement in resistance to scuffing as well as reduced wear when compared to conventional metallic pad materials (Lan *et al.*, 2016b, 2017). Enhancing the mechanical and thermal properties of the polymers using different additives such as carbon nanotubes, fiber glass, and graphene has also been demonstrated (Ye *et al.*, 2016).

Low inherent thermal properties of polymers lead to a drawback in their fitness for applications where high rates of frictional heat are generated. Heat generation due to friction in the pad bearings directly affects the lubrication film. Polymeric pads could act as thermal barriers and hinder the dissipation of generated heat thus affecting film thickness, generated bearing pressure, and maximum temperature. The effect of the thickness of the PTFE pads on the increase of temperature, and reduction in minimum film thickness was shown (Fillon and Glavatskih, 2008). However, such decrease could reduce the energy loss of the bearing (Wasilczuk and Rotta, 2013). Polymer-lined thrust bearings are viable substitutes for conventional White-metal or Babbitt pads and offer higher margin of safety through higher load capacity for the same size. In other words they are better counterparts to satisfy the higher power density of power generator machine requirements because of the smaller size they have compared to conventional pads for the same load capacity (Simmons *et al.*, 1998).

Another front that polymer lining of tilting pads deemed advantageous is water lubricated pads. Tribotesting of unfilled polymers in water lubricated conditions using a pin-on-disk configuration concluded that PTFE coating followed by Ultra-high-molecular-weight polyethylene (UHMWPE) showed the lowest COF respectively, and the abrasive wear mechanism was identified as the prevalent wear mechanism (Golchin *et al.*, 2013). Other studies focused on the possible problems that polymer materials such as PEEK could encounter in water lubricated conditions such as crack propagation and flaking (Xiao *et al.*, 2016).

Polymer Coating for Abrasive Wear Applications

Abrasive wear resistance of thin polymeric coating is also critical for some applications, as the thin coating might be penetrated and wear-out by the hard particles. Abrasive wear relates to cutting or plowing of the surface by harder particles or asperities (Myshkin *et al.*, 2005) and could be in the form of two-body abrasion, three-body abrasion or a combination of the two. Researchers applied different experimental protocols to evaluate abrasive wear resistance. In applications such as tilting pad bearings in ESPs in oil wells, or the drilling string in oil & gas drilling, the working conditions of the contacting surfaces are much more severe, compared to other experimental protocols (Shipway and Ngao, 2003; Harsha, 2011; Unal *et al.*, 2005). Thus, there is a need for aggressive experimental conditions to study the abrasive wear resistance of polymer coatings under such severe conditions/applications.

Fig. 4 Bearing pads lined with (a) PTFE blend (b) PEEK blend (diameter of 15 mm and thickness 2–3 mm). Reprinted from Wodtke, M., Wasilczuk, M., 2016. Evaluation of apparent Young's modulus of the composite polymer layers used as sliding surfaces in hydrodynamic thrust bearings. *Tribology International* 97, 244–252, with permission from Elsevier and (c) ATSP composite (diameter of 25 mm and thickness of 1 mm).

In the article of Lan *et al.* (2017), two advanced polymeric coatings (ATSP-based and PEEK-based) were selected and tested under severe sand abrasive conditions. A contaminated lubricant by sand (#140, 2 wt%) was used to simulate severe sand contaminated conditions such as those in ESPs. Under these conditions, ATSP exhibited superior wear resistance (wear rate of $6.1 \times 10^{-7} \text{ mm}^3 \text{ N}^{-1} \text{ m}^{-1}$). The abrasive sand worked as a solid lubricant causing a beneficial effect in the PEEK-based coating case, with a decrease in wear rate from $5.8 \times 10^{-6} \text{ mm}^3 \text{ N}^{-1} \text{ m}^{-1}$ under clean lubrication to $2.1 \times 10^{-6} \text{ mm}^3 \text{ N}^{-1} \text{ m}^{-1}$ in the presence of sand, albeit significantly higher than ATSP.

The tribological performance of ATSP-based coatings under much more severe abrasive conditions of oil & gas Extended Reach Drilling (ERD) applications (high contact pressure, high concentration of abrasives and high temperatures) has also been studied (Lan and Polycarpou, 2018). By utilizing its long horizontal section, ERD can reach offshore reservoirs from onshore drilling stations. Excessive drag that is generated by the rotational friction of the drill string on the wellbore limits the reach of the ERD technique. This drawback could lead to the reduction of production or the complete shutdown of a well. To reduce friction, ATSP-based coatings were applied on the disks (representing the drilling pipe) and pin-on-disk experiments were carried out. The results showed that the ATSP coatings reduce the COF at different temperatures ($\sim 58\%$ reduction), compared with bare substrate O1 tool steel material (see Fig. 5).

SEM/Energy Dispersive Spectroscopy (EDS) analyses showed that the particles embedded in the coating surfaces (Fig. 6) were solids that came from the drilling fluid, including barite and silica sand. These hard particles were embedded on the coating and could sustain the load and protect the coating from severe wear (Lan and Polycarpou, 2018). Meanwhile, the coating itself worked as a solid lubricant, thus the COF was lower, compared with the bare tool steel, especially at higher temperatures of 175°C .

Extreme Temperature Applications

Thin polymeric coatings are excellent candidates for extreme dry sliding conditions, where oil lubricants and greases are ineffective, such as for space applications. However, cryogenic and elevated temperatures encountered in space applications set a limit for a lot

Fig. 5 Tribological results of ATSP-based coatings and bare substrate in drilling fluid. of polymer materials. **Fig. 7** shows summary results of elevated temperature (23–260°C) dry condition tribological studies of ATSP-based coatings and PEEK-based coatings. ATSP-based coatings exhibited “zero wear” under these experimental conditions, except at 260°C and 10 N normal force for 430 m sliding distance; for PEEK-based coatings, due to the temperature effects on the hardness/flexibility, with increasing of the operating temperature, the abrasive wear became less important and the adhesive wear became more dominant, and at 180°C, the PEEK based coating formed a transfer layer that helped decrease both COF and wear rate (Lan *et al.*, 2016b).

The tribological performance of ATSP-based and PEEK-based coatings under cryogenic conditions, with temperatures as low as –160°C using a ball-on-disk experimental configuration, was also investigated (Lan *et al.*, 2018a). The COF of ATSP-based coatings increased with decreasing temperature, with a peak value at –100°C; similar to the elevated temperature experiments, the COF decreased when the load increased. The PEEK-based coatings showed 68% and 35% higher COF, compared to ATSP-based coatings at –40°C and –160°C, respectively. The experiments also showed that under cryogenic temperatures, both coatings exhibited near zero (immeasurable) wear.

SEM/EDS investigation revealed that the favorable transition (a decrease of COF for ATSP at –160°C with 10 N normal force) is due to the development of a polymer transfer film on the counter surface (see **Fig. 8**). While at low load of 5 N at the same temperature, transfer film did not develop after the same sliding distance, the higher load accelerated the development of the transfer film for the ATSP-based coating that consequently reduced the COF.

Micro/Nanomechanical Behavior of Polymeric Coatings

For tribological contacting/sliding surfaces, generally the top surface layers are the ones that determine the tribological performance in real-life applications. Thus, the measurement of the micro/nanomechanical properties of the top layers of bearing surfaces is critical in understanding their tribological behavior. Nano-indentation is a simple characterization technique to quantify the performance of such polymer surfaces (Yeo and Polycarpou, 2013).

Micro/Nano Indentation Results of Polymer Coatings

The Oliver-Pharr indentation method is a widely-used technique to measure the mechanical properties of materials, including thin films. In micro/nano indentation experiments, a rigid probe is pressed into the sample, and the transducer records the in-situ force and displacement responses. The elastic modulus can be obtained from the slope of the initial portion of the unloading curve and the hardness can be calculated by dividing the maximum indentation load with the contact area (Oliver and Pharr, 1992).

Fig. 7 Summary of ATSP/PTFE and PEEK/PTFE coating results: average COF vs wear rate, showing that ATSP/PTFE exhibits “zero wear” while PEEK/PTFE shows a higher wear rate. Data labels indicate material (ATSP or PEEK), test temperature, and normal load, sliding speed = 0.139 m s^{-1} . Reprinted from Lan, P., Meyer, J.L., Vaezian, B., Polycarpou, A.A., 2016b. Advanced polymeric coatings for tilting pad bearings with application in the oil and gas industry. Wear 354–355, 10–20 with permission from Springer Nature.

A phenomenological elevated temperature friction model for viscoelastic polymer coatings based on nanoindentation. *Tribology International* 119, 299–307, with permission from Elsevier.

Yeo and Polycarpou (2013) carried out micromechanical property measurements of different polymeric coatings; the load–unload responses were used to measure the load-bearing properties of the coatings, as well as to extract their elastic modulus and hardness values. The measured micromechanical properties of the various polymeric coatings tested showed that PEEK-based coatings exhibited higher elastic modulus than PTFE-based coatings, while their hardness values showed the opposite trend. Their tribological performance, however, was not directly related to their micromechanical properties, but rather to the coating structural uniformity (Yeo and Polycarpou, 2013). High temperature nanoindentation experiments (Lan *et al.*, 2018a) were conducted at the same elevated temperatures as in macro-scale ball-on-disk tribological experiments (Lan *et al.*, 2016a) at different temperatures (25°C, 100°C, 180°C, and 260°C). The two coatings showed decreasing hardness, elastic modulus and viscosity trends, with increasing temperature, as shown in Fig. 9. The ATSP coatings exhibited higher hardness, compared to the PEEK coatings, which correlated with ATSP's better wear resistance in the ball-on-disk experiments. In addition, to explaining the macro tribological performance, these micro mechanical properties can also be inserted into a friction model and the model showed reasonable COF prediction for the two coatings at higher temperatures, below the glass transition temperature.

Micro-Scratch Results of Polymer Coatings

Micro scratch experiments were conducted by penetrating and moving a diamond tip probe in the top layers (a few microns depth) of a sample and in-situ measurements of the normal and friction forces were recorded. The obtained forces help understand the microtribological behavior of the top layers. Micro-scratch experiments using a diamond conospherical probe with a tip radius of 4.3 μm were performed to further investigate the tribological behavior of ATSP and PEEK coatings (Lan *et al.*, 2017). The load function was a ramp load that applies a linearly increasing normal force, while it is moving laterally for a set distance. During the scratching process, the transducer records the in-situ normal displacement. The recorded normal displacement has both elastic and plastic deformations and is called in-situ displacement. The normal displacement as a function of normal load and the retrace steps provide information for the in-situ and residual depths, respectively. The recovery rate is an important and straightforward parameter to compare materials' resistance to plastic deformation or damage. This parameter is calculated by dividing the elastic recovery with the in-situ scratch depth. It varies from 0 to 1 or 0–100% (percentile scale). The larger the elastic recovery rate, the stronger the material's resistance to plastic deformation. The ATSP and PEEK coatings exhibit elastic recovery rates of 57.3% and 32.7%, respectively. The 24.6% higher elastic recovery rate of the ATSP coating makes it more scratch resistant, compared to PEEK coating.

Conclusion

The increasing usage of advanced polymer coating materials for tribological benefits in different industries were described. The inherent mechanical properties of the polymers were briefly discussed and their effect on their tribological performance was addressed. The application of polymers in bulk format and their advantages were summarized. Some of the state-of-the-art polymer coatings were introduced and their performance in air-conditioning and refrigeration compressors, thrust pad bearings, abrasive conditions, and extreme temperatures were presented and compared. Appropriate characterization techniques to obtain the micro mechanical properties of the thin coatings were discussed. The scope of the present article is to introduce some of the tribological applications of polymeric coatings. Specifically, ATSP, PEEK, and PTFE-based high bearing polymeric coatings are readily available, inexpensive and offer significant tribological advantages over a wide range of applications and conditions.

Waste Conversion Into Sustainable and Reinforcing Fillers for Rubber Composites

Introduction

Waste is inevitably produced by agriculture and industry. Increasing population and decreasing available space on earth, require that waste management is sustainable and economic. Landfill is a traditional method of waste disposal, but land contamination and high cost make this method unsustainable. Waste has been combusted to replace petroleum as an energy source but greenhouse gases are vented and ash residuals still remain. Furthermore, not all wastes can be burnt. Recycling and repurposing are ideal waste management strategies, because they can increase waste value and prevent pollution. Low price and abundant supply make wastes attractive for high volume uses, such as alternative fillers for rubber and plastic composites.

Rubber is one of the most important and widely used materials. Although rubber, itself, possesses excellent impact strength and elasticity, rubber still needs to be reinforced by fillers to further improve its mechanical properties for many applications. The properties of rubber composites are highly related to the characteristics of their fillers. Carbon black (CB) and high surface area precipitated silica (PS) are the most commonly used reinforcing fillers in rubber composites (Leblanc, 2002). Both PS and CB have reinforcing effects on rubber composites. As synthetic fillers, CB and PS are expensive and cause environmental problems. Also, U.S. CB supply is facing a shortage because of increasing consumption and environmental concerns, and the shortfall may be as much as 0.2 million tons by 2025 (Moore, 2018). The price of CB has increased steadily for nearly 20 years, in parallel to the producer price index increase from 83.1 in 1990 to 329.8 in 2018 (U.S. Bureau of Labor Statistics, 2018). The high price of CB has a profound effect on rubber product cost. The price of PS faces a similar situation and one of the biggest global silica suppliers, PPG, announced that the price of silica products will increase by up to 6% in 2018 (PPG, 2017). Therefore, manufacturers using PS and CB are interested in their partial or complete replacement by alternative fillers which are low-cost and environmentally friendly (Table 1).

Neither PS nor CB are renewable, but waste-derived fillers with ready availability and low price are easily obtained from agricultural and industrial production facilities. Replacing CB and PS fillers and developing new rubber composites with waste-derived fillers would mitigate carbon emissions. On a production scale, it is likely that waste-derived fillers could be produced much less expensively than PS (\$500-800/ton) or CB (\$720-730/ton) (Bashir and Manusamy, 2015; Jinzhou Hancheng Chemicals Co, 2017; Weifang Longstar Economy And Trading Co, 2017). Furthermore, the new rubber composites may not only match current commercial rubber product properties, but evince new combinations of properties (Barrera and Cornish, 2016a, 2017b). These may open new markets and further increase the value of the wastes used to make the fillers.

Curing behavior and reinforcing effects of fillers are studied to characterize rubber composites and determine their potential usefulness. Usually, scorch and cure time, and minimum and maximum torque are measured to describe the curing behavior. Scorch time is the time during which a rubber compound can be worked at a given temperature without scorching before curing begins and indicates that the material has been partially vulcanized and that its plasticity has been reduced. The rubber material can't be reprocessed after the scorch time. Cure time is the time needed for the rubber to vulcanize sufficiently to reach its optimal properties. Torque indicates the resistance of the sample during curing to shear stress. During vulcanization, the rubber molecules are crosslinked by curing agents, usually sulfur. Crosslink density (the number of rubber diene monomers between the cross-linking points) is used to quantify the degree of vulcanization. Reinforcing effects of waste fillers are measured by their mechanical and dynamic mechanical properties. Tensile strength, elongation at break, modulus and hardness characterize the mechanical properties, whereas storage modulus, loss modulus and $\tan \delta$ in specific temperature or frequency ranges characterize the dynamic mechanical properties.

Silica-Based Fillers in Rubber Composites

Background

Silicon is one of the most abundant elements on the earth. Silicon dioxide, also called silica, is the main residue from the combustion process of thermal power generation, due to its heat stability. Coal is the fossil fuel generally used to generate electricity, and co-produces large amounts of fly ash (FA) (Ren, 2016). The main components of FA are silica (39.7%–51.1%) and metal oxide (41.4%–60.6%) (Blissett and Rowson, 2012). Annually, over 750 million tons of FA is produced in the world (Gwon *et al.*, 2017). Without proper management, FA can cause air pollution by releasing dust into the atmosphere; it is traditionally disposed of by landfill, but expensive landfill fees and massive land occupation encourage utilization of FA

Table 1 Comparison between CB, PS and waste fillers

	CB	PS	Waste fillers
Production	Incomplete combustion of petroleum oil under high temperature (5.7 kg carbon dioxide per kg CB) (Lockwood and Van Niekerk, 1995; Rodat <i>et al.</i> , 2011)	Precipitated reaction of silicates in sulfuric acid (Schlomach and Kind, 2004)	Byproducts from agricultural and industrial productions
Price	High and increased (U.S. Bureau of Labor Statistics, 2018)	High and increased (PPG, 2017)	Low
Reinforcing effect on rubber composites	Improved strength, modulus and abrasion resistance of rubber composites (Kohls and Beaucage, 2002)	Reduced rolling resistance combined with high tear strength and abrasion resistance (Hashim <i>et al.</i> , 1998)	Dependent on filler size, chemical structures and surface morphology

(Blissett and Rowson, 2012). For example, FA has been used in self-compacting concrete, which has good deformability and segregation resistance (Siddique *et al.*, 2016).

Silica based fillers also can be obtained from agricultural byproducts. Rice husk is a byproduct of rice-milling processes. About 28% of rice is husk and 200 million tons of rice husk was produced in 2017 (Lane, 2017). Generally, rice husk is used as fuel to generate power. After combustion, white rice husk ash (WRHA) and black rice husk ash (BRHA) are both produced as residuals. WRHA is produced as the inner part of the rice husk ash (RHA) because of the higher temperature, while BRHA forms the outer layer of RHA (Ishak and Bakar, 1995). WRHA possesses a higher silica fraction (96%) than BRHA (54%), which also contains 44% carbon (Ismail *et al.*, 1999a,b). These RHAs also contain less than 3% metal oxides (Ishak and Bakar, 1995).

Oil palm is the highest yielding oil crop, and its oil is the second most traded vegetable oil in the world after soybean oil (Sumathi *et al.*, 2008). Palm oil production cogenerates a large amount of solid waste, much of which is burnt to generate electricity leaving oil palm ash (OPA). In Malaysia alone, OPA production is 4 million tons/year (Foo and Hameed, 2009). Disposal costs are significant in both developing (\$5/ton) and developed countries (\$50/ton), and so converting OPA into value-added materials is important (Foo and Hameed, 2009). OPA contains similar amounts of silicon dioxide (37%–63.6%) to BRHA, as well as metal oxides (calcium oxide, aluminum oxide, iron oxide, magnesium oxide, sodium oxide and potassium oxide) (21.5%–49.3%) (Foo and Hameed, 2009).

Silica-rich FA, RHA and OPA may have utility as waste-derived fillers in rubber composites as substitutes for precipitated silica.

Curing Behavior

Silica-based fillers affect curing behavior differently depending upon the type of rubber. In general, they significantly retard the vulcanization of rubber composites, because the essential chemical accelerators in the compounds can react with the silica instead of the rubber molecules (Mukhopadhyay and De, 1979; Ismail *et al.*, 1999a,b; Sombatsompop *et al.*, 2004; Raji Vijay *et al.*, 2016). The cure time of natural rubber (NR) from the *para* rubber tree (*Hevea brasiliensis*) (HNR) is independent of FA filler loading (Sombatsompop *et al.*, 2004), while the cure time of styrene butadiene rubber (SBR) is reduced as FA loading increases (Sombatsompop *et al.*, 2004). The scorch and cure times of OPA-filled HNR become faster with increasing OPA content (Ismail and Haw, 2008; Ooi *et al.*, 2013a,b). The faster cure and scorch times occur because the high metal oxide levels (calcium oxide, aluminum oxide and magnesium oxide) in the FA and OPA silica-based fillers act as vulcanization rate accelerators. This does not occur in RHA filled HNR composites (Da Costa *et al.*, 2002) because of their low metal oxide content.

Surface modification with silane coupling agents is generally used to improve the interaction of silica fillers with rubber and so enhance their reinforcement of the composite material (Wang, 1998; Ansarifar *et al.*, 2003). Silane coupling agents have tetrasulfane and ethoxy groups: the tetrasulfane groups react with double bonds on rubber molecules to form –S–C– bonds, while the ethoxy groups react with the silanol groups to form –Si–O– bonds. Since FA has silica as a major component, silane modification can be used to improve its interaction with rubber. However, as silane content increases, the cure and scorch times of FA-filled HNR composites slow (Thongsang and Sombatsompop, 2006). This is believed to be caused by reactions between unsaturated groups, like carbon-carbon double bonds, in HNR and silane's tetrasulfane groups, instead of with the sulfur, limiting the formation of sulfur crosslinked macromolecular structures. In addition, the large size of silane molecules may sterically hinder the reaction between sulfur and HNR molecules (Poh and Ng, 1998). Maleated HNR, when used as a coupling agent, also improves the reinforcement of HNR composites by OPA. Scorch and cure times further slow with increasing coupling agent content, which can be explained by the strong interaction between OPA and rubber by coupling agent (Ismail and Haw, 2008).

The silanol groups on silica form a hydrogen bonded filler network (Wang, 1998), which increases both minimum and maximum torque of PS filled rubber composites. The other silica-based fillers have different effects on the curing behavior. The minimum torque is unaffected but maximum torque increases with increasing FA content in HNR and SBR composites (Sombatsompop *et al.*, 2004). OPA-filled HNR composites have similar torque changes to those in FA composites, which are caused by the reduction of the movement of rubber chains (Ooi *et al.*, 2013a). Both FA and BRHA reduce maximum and

Table 2 The changes of minimum torque and maximum torque of rubber composites with increasing content of silica-based fillers (all values were compared to the unfilled rubber composites)

Filler	Size (μm)	Rubber matrix	Minimum torque	Maximum torque
FA (Sombatsompop <i>et al.</i> , 2004)	50–100	HNR	No change	Increased 0%–200%
PS (Sombatsompop <i>et al.</i> , 2004)	Not mentioned	HNR	Increased 0%–730%	Increased 0%–410%
FA (Sombatsompop <i>et al.</i> , 2004)	50–100	SBR	No change	Increased 0%–100%
PS (Sombatsompop <i>et al.</i> , 2004)	Not mentioned	SBR	Increased 0%–830%	Increased 0%–420%
OPA (Ooi <i>et al.</i> , 2013a)	41	NR	Increased 0%–40%	Increased 0%–10%
WRHA (Da Costa <i>et al.</i> , 2002)	2	NR	Reduced 0%–210%	Increased 0%–30%
BRHA (Da Costa <i>et al.</i> , 2002)	3	NR	Reduced 0%–120%	Increased 0%–20%
PS (Da Costa <i>et al.</i> , 2002)	0.018	NR	Increased 0%–370%	Increased 0%–30%
OPA (Ismail and Haw, 2008)	75	Maleated HNR	Increased 0%–230%	Increased 0%–50%

minimum torque less than PS because of their weaker filler-filler interactions (Da Costa *et al.*, 2002; Sombatsompop *et al.*, 2004). Maleated HNR increases both the minimum and maximum torques of HNR composites with increasing OPA content, because of the increased filler-rubber interaction (Ismail and Haw, 2008) (Table 2).

Reinforcing Effect on Mechanical Properties

Unmodified FA poorly reinforces rubber composites, decreasing the tensile strength, elongation at break and tear strength, compared to unfilled HNR (Sombatsompop *et al.*, 2004). The large FA particle size (50–100 μm) and poor rubber-filler interaction explains the inferior tensile strength, elongation at break, hardness and modulus, compared with PS. At low filler loading of OPA (less than 1 phr) and RHA (less than 30 phr) filled HNR composites, tensile strength and elongation at break increase (Ishak and Bakar, 1995; Ooi *et al.*, 2013b). The increased mechanical properties were explained by the full wetting of the OPA and RHA by the NR matrix (Ooi *et al.*, 2013b). As filler content further increased, the mechanical properties decreased due to poor filler dispersion (Ismail and Haw, 2008; Ooi *et al.*, 2013b). WRHA filled NR composites exhibit higher tensile strength, modulus at 300% strain, elongation at break and tear strength than BRHA, though BRHA has smaller particle size (Ishak and Bakar, 1995). Both WRHA and BRHA filled NR composites have higher tear strength but lower tensile strength, modulus at 300% strain and hardness than CB (Sae-Oui *et al.*, 2002). The inferior reinforcing effect of RHA is caused by the large filler particle size and greater filler agglomeration. OPA filled NR composites have lower hardness and tensile modulus than PS and CB (Ooi *et al.*, 2013a). The high stiffness of CB filled NR composites is due to the small particle size of CB. However, OPA filled NR also exhibits higher tensile strength and elongation at break than PS (Ooi *et al.*, 2013a) (Table 3).

As silane concentration increases, tensile strength, modulus and tear strength of PS filled rubber composites also increase, because the coupling agent increases the rubber-filler interaction (Thongsang and Sombatsompop, 2006). However, the silane treated FA still has weaker rubber-filler interaction than silane treated PS. Tensile strength, modulus at 300% strain, elongation at break, tear strength and hardness reduce, as FA partially or completely replaces PS in HNR composites (Thongsang *et al.*, 2012). Silane-modified RHA-filled HNR still possesses lower tensile strength and modulus than CB and PS filled HNR, which is due to fewer silanol groups on the RHA surface (Sae-Oui *et al.*, 2002). The multifunctional additive (n-fallow-1-3-propanediamine salt) also acts as a coupling agent in RHA-HNR composites, up to 5 phr, increasing tensile strength, modulus at 300% strain and tear strength (Ismail *et al.*, 1999a,b).

Maleated HNR can form hydrogen bonds with silanol groups on the OPA surface, and is miscible with HNR (Ismail and Haw, 2008). The hydrogen bonds enhance the wettability and attachment of OPA with HNR, increasing elongation at break, modulus, tensile strength and fatigue life (Ismail and Haw, 2008). The improved HNR-OPA interaction also is supported by scanning electron microphotographs of fracture surfaces (Fig. 1).

Nano-sized FA (148 nm), produced by high energy milling, reinforces SBR more than CB, precipitated silica or unmilled FA (60–100 μm) (Paul *et al.*, 2009), and the composites have higher modulus, tensile strength and hardness. The fracture surfaces of scanning electron micrographs and bound rubber evince the uniform dispersion and strong rubber filler interaction of nano-sized FA filled SBR. As FA size reduces from macro (89 μm) to micro (12 μm), modulus at 300% and tensile strength of HNR and GNR composites increase (Barrera and Cornish, 2015, 2016a). However, tensile strength, modulus at 300% strain and elongation at break of HNR and GNR composites decrease with the reduction of FA size from micro (12 μm) to nano (218 nm) (Barrera and Cornish, 2017b). The poor reinforcement by nano FA was explained by increased attraction between FA particles (Fig. 2).

RHA also reinforces thermoplastic elastomers (rubber/plastic composites). As RHA content increases from 0 to 25 phr, tensile strength, elongation at break, tensile modulus and hardness of SBR/linear low-density polyethylene composites increase (Khalf and Ward, 2010). The increased mechanical properties of thermoplastic elastomers are related to enhanced interfacial interaction between the polymer matrix and RHA, caused by the coupling agent, maleic anhydride. RHA also increases the Young's

Table 3 The changes of mechanical properties of rubber composites with increasing content of silica-based fillers (all values were compared to the unfilled rubber composites)

Waste filler	Size (μm)	Rubber matrix	Tensile strength	Elongation at break	Tear strength	Modulus at 300% strain
Unmodified FA (Sombatsompop <i>et al.</i> , 2004)	50–100	NR	Reduced 0%–90%	Reduced 0%–60%	Reduced 0%–60%	Fluctuated, little change
WRHA (Ishak and Bakar, 1995)	5	Epoxidized NR	Increased 0%–110%, then decreased	Increased 0%–20%, then decreased	Increased 0%–30%, then decreased	Increased 0%–100%
BRHA (Ishak and Bakar, 1995)	2	Epoxidized NR	Increased 0%–90%, then decreased	Increased 0%–20%, then decreased	Increased 0%–30%, then decreased	Increased 0%–140%
OPA (Ooi <i>et al.</i> , 2013a)	41	NR	Increased 0%–20%, then decreased	Increased 0%–10%, then decreased	Unknown	Increased 0%–20%

**Fig. 1** SEM microphotographs of the tensile-fractured surface of 30 phr OPA filled SMR L/MANR blends with different weight ratios: (a) 100/0, (b) 5/95, (c) 10/90, and (d) 20/80 (magnification=300 $\times$). From Ismail, H., Haw, F.S., 2008. Effects of palm ash loading and maleated natural rubber as a coupling agent on the properties of palm-ash-filled natural rubber composites. *Journal of Applied Polymer Science* 110 (5), 2867–2876.

modulus but decreases the tensile strength and elongation at break of unfilled epoxidized HNR/thermoplastic polyurethane blends (Pongdong *et al.*, 2016). The enhanced modulus is attributed to hydrodynamic effects and chemical bonds between polar functional groups of RHA and polymer matrix (Table 4).

Cellulose-Based Fillers in Rubber Composites

Background

Natural fibers, such as oil palm fiber (OPF), sisal fiber (SF) coir fiber (CF), and tomato peels (TP), are lightweight, high-modulus, non-toxic materials which absorb carbon dioxide during their growth (Kabir *et al.*, 2012). Natural fiber is a common construction material for roofing and cladding (Frazão *et al.*, 2018), but production is far greater than consumption (Geethamma *et al.*, 2005). Thus, new large scale applications of natural fibers are needed, perhaps including their use as fillers in composites.

Oil production from oil palm in 2006 reached 36.9 million tons (Sumathi *et al.*, 2008), with 31.8 million tons of coproduced OPF (Karina *et al.*, 2008; Shinoj *et al.*, 2011). The main components of OPF are cellulose (42.7%–65.0%) and lignin (13.2%–25.3%) (Shinoj *et al.*, 2011). Sisal is a native plant of Mexico and SF, mainly composed of cellulose (78%) (Frazão *et al.*, 2018), and 4.5 million tons is produced per year (Li *et al.*, 2000). Coconut is an important natural resource for food, cosmetic and charcoal production and coconut processing coproduces 0.75 million tons of CF annually (Rejeesh and Saju, 2017). The main components of CF are cellulose

Table 4 The changes of mechanical properties of thermoplastic composites with increasing content of RHA (all values were compared to the unfilled thermoplastic composites)

Waste filler	Size (μm)	Rubber matrix	Tensile strength	Elongation at break	Tear strength	Modulus at 300% strain
RHA (Khalf and Ward, 2010)	Unknown	SBR/linear low-density polyethylene blends	Increased 0%–170%, then decreased	Increased 0%–60%, then decreased	Unknown	Increased 0%–70%, then decreased
RHA (Pongdong et al., 2016)	4	HNR/thermoplastic polyurethane blends	Decreased 0%–30%	Decreased 0%–90%	Unknown	Increased 0%–20%

(30%–45%) and lignin (30%–45%). TP is an agricultural byproduct from food industry. In the U.S. in 2017, 29 million metric tons of tomatoes were produced with over 100 thousand metric tons of TP coproduced (the peel yield is 7%–10% of tomato weight) (Ayvaz et al., 2016; USDA, 2018).

Curing Behavior

The addition of OPF has no significant effect on the scorch and cure times of HNR composites (Ismail et al., 1997). The maximum and minimum torques increase with increasing OPF loading, because the stiffness of OPF filled HNR composites also increases. The cure time of OPF filled HNR composites increases in a tricomponent coupling system (silica, resorcinol formaldehyde and hexatetramine) due to the enhanced rubber-OPF interaction (Ismail et al., 1997). TP filled HNR and GNR composites have lower crosslink density than CB (Barrera and Cornish, 2016b, 2017b), because CB can form more crosslink structures by physical interaction with the rubber matrix (Fröhlich et al., 2005) than can the other two fillers.

Table 5 The changes of mechanical properties of rubber composites as increasing the content of cellulose-based fillers (all values were compared to the unfilled rubber composites)

Waste filler	Size (μm)	Rubber matrix	Tensile strength	Elongation at break	Tear strength	Tensile modulus
OPF (John <i>et al.</i> , 2008)	150–500	HNR	Reduced 0%–120%	Reduced 0%–20%	Increased 0%–110%	Increased 0%–50%
Sodium hydroxide treated OPF (John <i>et al.</i> , 2008)	150–500	HNR	Reduced 0%–30%	Reduced 0%–50%	Increased 0%–190%	Increased 0%–250%
Silane treated OPF (John <i>et al.</i> , 2008)	150–500	HNR	Reduced 0%–30%	Reduced 0%–50%	Increased 0%–160%	Increased 0%–230%
Hybrid filler of OPF and SF (1:1 mixture by weight) (Jacob <i>et al.</i> , 2004)	OPF: 150–500 SF: 120	HNR	Reduced 0%–50%	Reduced 0%–10%	Increased 0%–100%	Increased 0%–240%
TP (Barrera and Cornish, 2016a)	23	GNR	Increased 0%–160%	Increased 0%–50%	Unknown	Increased 0%–20%
TP (179 μm) (Barrera and Cornish, 2016a)	179	GNR	Reduced 0%–40%	Reduced 0%–10%	Unknown	Reduced 0%–20%
TP (Barrera and Cornish, 2017a)	0.386	GNR	little change	Reduced 0%–40%	little change	Increased 0%–130%

Reinforcing Effect on Mechanical Properties

Tensile strength, elongation at break and tear strength decrease, but modulus and hardness increase, as OPF loading increases in HNR rubber composites (Ismail *et al.*, 1997; John *et al.*, 2008), due to the poor wettability of OPF by the HNR matrix and interruption of strain induced crystallization (John *et al.*, 2008). A hybrid filler of OPF and SF (1:1 mixture by weight) increases tear strength and modulus, but decreases tensile strength and elongation at break compared to unfilled HNR (Jacob *et al.*, 2004). The hybrid fiber has an optimal fiber loading of 30 phr, which maximizes tensile strength, elongation at break and tear strength but is still lower than unfilled HNR. At lower hybrid fiber loading, the distance between fibers is too far to transfer stress from the rubber matrix, which results in load concentration and material failure. Higher hybrid fiber loading contributes to agglomeration of the fibers, which blocks load transfer (Jacob *et al.*, 2004). Reinforcement by OPF and SF also is dependent on fiber length, with best performance at 10 mm OPF and 6 mm SF (Jacob *et al.*, 2004; John *et al.*, 2008). Longer fibers entangle and reduce mechanical properties of composites (Jacob *et al.*, 2004). TP (23 μm) filled GNR has similar tensile strength, hardness and higher elongation at break to CB composites with less than 60% CB replacement (Barrera and Cornish, 2016a, 2017b). The irregularity of TP increases the rubber-filler interaction (Barrera and Cornish, 2016a). In contrast, TP reduces the tensile strength and modulus of HNR composites as CB is replaced (Barrera and Cornish, 2015). The branched structure of HNR may block the load transfer from HNR to TP and explain the poorer reinforcement of TP in this type of rubber (Barrera and Cornish, 2016a). CF is the poorest reinforcing fibrous filler among these different fibers because of its high microfibrillar angle and large diameter (Geethamma *et al.*, 1998) (Table 5).

Modification of cellulose-based fillers can improve their reinforcement effects. Sodium hydroxide (4%–5%) treated fibers in HNR composites improve tensile strength, elongation at break, modulus and hardness more than untreated OPF, SF and CF (Geethamma *et al.*, 1998; John *et al.*, 2008). Alkali treatment breaks fiber bundles and decreases fiber size, which increase the interfacial area between rubber and fiber (Li *et al.*, 2000). Also, the alkali treatment produces voids by reacting with the globular protrusions which exist on the surface of CF enhancing the surface roughness of CF (Geethamma *et al.*, 1998, 2005). Thus, the interfacial area and adhesion between fiber and rubber matrix increases (Geethamma *et al.*, 1998; Li *et al.*, 2000), resulting in more efficient stress transfer from the rubber matrix to the fiber (John *et al.*, 2008). On the other hand, high concentrations of sodium hydroxide (more than 8%) result in OPF degradation and deterioration of mechanical properties of HNR composites (John *et al.*, 2008). Tensile strength of 5% alkali treated CF decreases as CF increases up to 30 phr, then increases (Geethamma *et al.*, 1998). Insufficient stress transfer explains the low tensile strength at lower CF loadings, while high fiber loadings restrain the rubber matrix. Sodium hydroxide-treated CF filled HNR composites exhibit two obvious $\tan \delta$ peaks at low and high temperature, which correspond to the HNR and CF. The loss modulus and $\tan \delta$ increase with increasing CF loading from 0 to 60 phr, because of increased energy dissipation under dynamic conditions (Geethamma *et al.*, 2005). The interfacial area between CF and the rubber matrix becomes larger with more CF loading, which results in more energy dissipation in the HNR composites. The $\tan \delta$ peak of CF filled HNR composites moves towards higher temperature as fiber loading increases, corresponding to a higher glass transition temperature (Geethamma *et al.*, 2005) (Fig. 3).

Silane coupling agent also improves the reinforcing effect of the hybrid filler of OPF and SF, but their performance is still lower than unfilled HNR (John *et al.*, 2008). The silane forms chemical bonds between the rubber matrix and the fibers, as the silane forms silanol groups in the presence of water, which then react with the hydroxyl groups on the surface of the OPF and SF. The functional groups of the silane coupling agent, such as amino group or fluorine, also can form hydrogen bonds with HNR (John *et al.*, 2008).

Fig. 3 SEM microphotographs of TP (23 μm). Figure from Barrera, C.S., Cornish, K., 2016a. High performance waste-derived filler/carbon black reinforced guayule natural rubber composites. *Industrial Crops and Products* 86, 132–142.

Physical treatment also significantly affects NR reinforcement by TP (Barrera and Cornish, 2016a, 2017b; Barrera *et al.*, 2018). Tensile strength, modulus at 300% strain and elongation at break of GNR composites increase with decreasing TP particle size from macro-size (179 μm) to micro-size (23 μm) as the TP-GNR interaction increases (Barrera and Cornish, 2016a). However, tensile strength and elongation at break of GNR composites all decline in nano-TP filler (386 nm), due to the increased filler-filler interactions among the polar functional groups on the TP surface (Barrera and Cornish, 2017b).

Calcium Carbonate-Based Fillers in Rubber Composites

Background

Calcium carbonate is a common filler in rubber composites largely as a diluent filler. However, calcium carbonate-based waste fillers, like ES, increase elongation at break and tensile strength, while production cost is reduced (Saeb *et al.*, 2013; Barrera and Cornish, 2017b). Commercial calcium carbonate is produced by mining or chemical precipitation, and both methods are energy intensive, nonrenewable and emit greenhouse gases (Klungsuwan *et al.*, 2013). Thus, calcium carbonate fillers from renewable resources are desired to help establish sustainable rubber composites. Marine products and eggs are two potential sources.

As an important protein source, eggs are consumed globally. The United States produces over 100 billion eggs every year (United States Department of Agriculture, 2017). The average weight of an egg is 60 g, and each egg includes about 11% eggshell (ES) (Tsai *et al.*, 2006). Thus, about 0.7 million tons/yr of ES are produced as food waste in the U.S. ES waste produced by the food processing industry is mainly landfilled, which is neither economic nor eco-friendly (Carvalho *et al.*, 2011; Iyer and Torkelson, 2014). ES fillers, used on a large scale, would reduce the cost and pollution of disposal (Mičicová *et al.*, 2016). The chemical composition of ES is 94% calcium carbonate, 1% calcium phosphate, 1% magnesium carbonate and 4% organic matter (protein fibers and mucin protein) (Tsai *et al.*, 2006). Since calcium carbonate is used as a non-reinforcing diluent filler (as a polymer extender) in rubber products, ES may be an alternative source. In addition, ES have high porosity, developed to support the high gas exchange needed to allow developing chicks to respire efficiently (Wangenstein *et al.*, 1970; Barrera and Cornish, 2015), and this architecture persists in micro ES particles, which increases the interfacial area between ES and rubber.

Cuttlefish is a common food in tropical countries. The skeleton of cuttlefish or cuttlebone is a byproduct from food industry and consists of 91% calcium carbonate and 8% protein and chitin (Poompradub *et al.*, 2008). Cuttlebone particles also may be an alternative filler to calcium carbonate in rubber composites.

Curing Behavior

The alkalinity of calcium carbonate can accelerate the vulcanization process (Baranwal and Stephens, 2001; Klungsuwan *et al.*, 2013; Barrera and Cornish, 2017b). During vulcanization, the maximum torque and crosslink density are enhanced but the scorch and optimum cure times decrease with increasing ES and cuttlebone loading in untreated and epoxidized HNR and SBR composites (Poompradub *et al.*, 2008; Intharapat *et al.*, 2013; Klungsuwan *et al.*, 2013; Barrera and Cornish, 2016a). ES filled rubber composites have higher maximum torque, and shorter scorch and cure optimum times, than commercial calcium carbonate (Intharapat *et al.*, 2013), which is attributed to the accelerating effect of metal oxides and amino acids in ES (Intharapat *et al.*, 2013; Saeb *et al.*, 2013). Also, ES proteins can form hydrogen and covalent bonds with the oxirane rings of epoxidized HNR. Stearic acid coated ES reduces the scorch time of HNR and SBR, but with no significant effect on cure optimum times (Saeb *et al.*, 2013).

Table 6 The changes of mechanical properties of rubber composites as increasing the content of calcium carbonate-based fillers (All values were compared with the unfilled rubber composites)

Waste filler	Size (μm)	Rubber matrix	Tensile strength	Elongation at break	Tear strength	Hardness
ES (Intharapat <i>et al.</i> , 2013)	26	Epoxidized HNR	Reduced 0%–30%	Reduced 0%–20%	Reduced 0%–10%	Increased 0%–20%
ES (Saeb <i>et al.</i> , 2013)	0.349	HNR	Increased 0%–30%	Reduced 0%–10%	Unknown	Unknown
ES (Saeb <i>et al.</i> , 2013)	0.349	SBR	Increased 0%–40%	Increased 0%–25%	Unknown	Unknown
Cuttlebone (Klungsuwan <i>et al.</i> , 2013)	106	HNR	Increased 10%, then reduced 40%	Fluctuated, then reduced 40%	Unknown	Increased 30%

Reinforcing Effect on Mechanical Properties
